The Luo rulers and such followers as had accompanied them were soon fully absorbed into the Bantu population of these kingdoms. Immediately to the north (where the Bantu did not extend) there occurred the greatest independent expansion of the Luo peoples, who formed the Acholi; provided ruling groups for peoples to the west who came to be called Alur; and bred the Jopaluo and Jopadhola to the east and also the sizable Luo populations who, between the mid-16th and the mid-18th centuries, came to settle on the northern side of Winam Bay to the northeast of Lake Victoria and spread thereafter to its southern shore as well.

Over to the east, into the former Cushitic domain that centred upon the Rift Valley, there appears to have been, in about the middle of the present millennium, a great expansion of Kalenjin peoples. These Highland Nilotes (as distinguished from, among others, River–Lake Nilotes such as the Luo), seem to have absorbed most of the previous southern Cushites who remained there and also to have successfully held the core of this ancient wedge, if not its earlier dimensions, against further Bantu incursions. By 1700, however, a second expansion into this old protrusion was beginning. During the 18th century the Masai (Plains Nilotes, as they are now being called) spread over most of the area, until they came to be found as far south as Gogo country in central Tanzania. Already divided into pure-pastoralist and mixed-agriculturist subtribes, they were soon to be found to the east near Kilimanjaro. The earlier Kalenjin thus found themselves confined to the hillier country between the Rift Valley and Lake Victoria, where—constituting the Keyu (Elgeyo), the Suk

Expansion of the Masai

(Pokot), the Nandi, the Kipsikis, and the Tatoga of more recent times—they entered into a variety of interactions with their various Luo and Bantu neighbours. Farther to the north in the areas beyond Mount Elgon a shorter-run series of migrations by other Plains Nilotes was simultaneously taking place. First, in the 17th century, the Lango began moving southwestward (and became much affected by their River–Lake Nilotic neighbours, the Acholi). Then, in the 18th century, the Teso, Karamojong, and others began also to move in various southward directions.

It has been suggested that all these Highland and Plains Nilotic migrations were set off, both before and after the middle of the present millennium, by successive pressures from the Cushitic Oromo to the north. Like the Oromo, the Nilotic peoples lacked any firmly institutionalized political power, and their leaders were often less important than the elders of their clans. Indeed, Nilotes established "states" only where, as in the interlacustrine area over to the west, they came to rule other peoples who may very well have had traditions of rulership before they arrived. Such distinctions were to be of immense importance for the future.

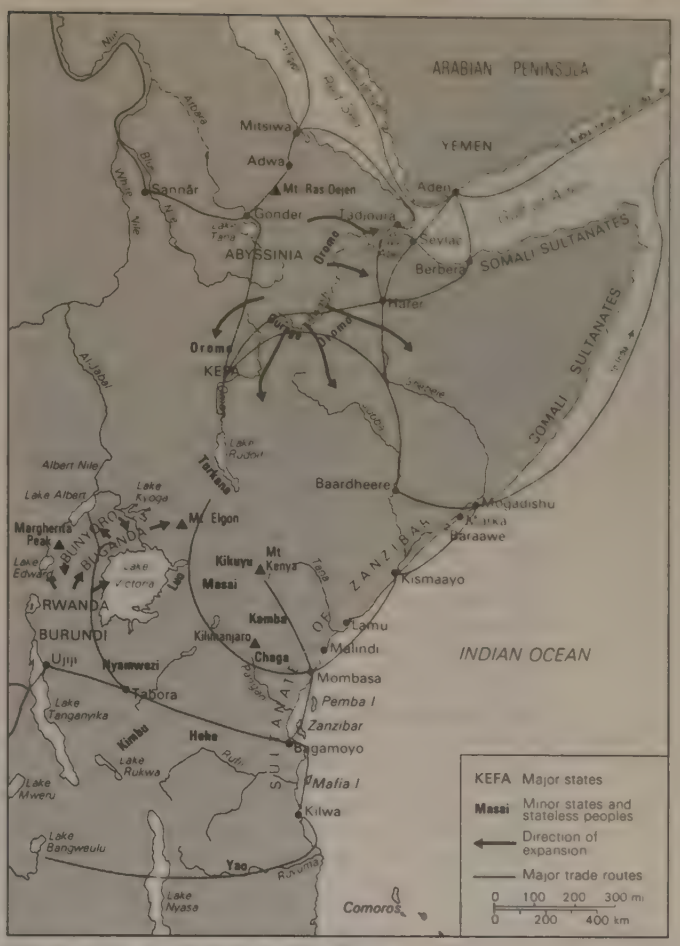
Pressure on the southern chieftainships. With the breakup of their main body, at the north end of Lake Nyasa, after 1845, some parties of Ngoni moved northward. Some Ngoni groups made their way to Songea; another struck north to Lake Victoria. They carried, to the area west of Lake Tanganyika, a new style of raiding and appear to have precipitated among such peoples as the Hololoho and the Ndendehule, the Sangu, and the Bena—in part, at least, as a safeguard against Ngoni raids—the creation of new political institutions, including more powerful rulerships. The most notable of such developments were, in the first place, among the Hehe, where, under Munyigumba and then on his death, in 1879, under his son Mkwawa, a powerful state was built up; then among the Nyamwezi, where between 1870 and 1884 the warrior chief Mirambo established a powerful personal rulership; and also among the Kimbu, where, between 1870 and 1884, Nyungu and his *ruga-rugas* (or bands of warriors) created a dominion that survived his death.

Nothing quite so striking occurred to the northeast. Conflict persisted between the smaller Chaga rulers on Kilimanjaro. In the mid-19th century, Kimweri enjoyed a considerable dominion in the region of the Usambara Mountains, but on his death in the 1860s his rulership disintegrated. Further such disintegrations occurred in the 19th century among the rulerships of Buha and Buzinza, at the south end of Lake Victoria, and among the Buhaya kingdoms on its eastern shore. The kingdom of Mpororo, to the west of Buhaya, had already broken up. By the 1890s its neighbour Nkore seems to have been in danger of disintegrating as well. Earlier in the century Toro, to its north, had broken away from Bunyoro, previously the most extensive of the kingdoms in this area, while fragmentation was almost endemic among the Busoga kingdoms to the east.

Decline of northeastern kingdoms

Rwanda and Buganda. But there were also growing points in the interlacustrine area, where one of the largest kingdoms, Rwanda, consolidated its rear by annexing Lake Kivu, then, in the aftermath of a succession war, swallowed the small kingdom of Gissaka, to its east. It failed to defeat Burundi, to the south, but under its mwami, or ruler, Kigeri IV (who reorganized its military forces) it extended its control by raiding to the north.

Its power was equaled in this region only by the kingdom of Buganda. Having annexed the large area of Buddu, to its southwest, in the late 18th century, Buganda thereafter generally refrained from any further territorial extensions. Its rulers steadily increased their authority at home by enhancing the power of appointed chiefs at the expense of the clan leaders, while abroad they preferred to make satellites rather than subjects of their neighbours. They had a good deal of success eastward in Busoga and southward along the western shore of Lake Victoria and around its southern rim. In the 1870s and '80s Buganda's protégés were on several occasions installed in petty rulerships in Busoga. In 1869 Bunyoro successfully survived Buganda interference in one of its succession conflicts (as Nkore did in 1878) and indeed in the 1870s and '80s was renewing its strength. Bunyoro's improved position turned much on its new military formations, the *abarasura,* while Buganda's successful predation owed a good deal to its new military efforts under the *mujasi,* or military commander, as well as to the building of a formidable fleet of canoes.



Major states, peoples, and trade routes of eastern Africa, *c.* 1850.

The Luo and Masai. To the north and northeast the previous migrations of the Luo from west to east were followed in the 19th century by a new wave of migrations from east to west. The Lango, for example, further expanded in two southward and westward waves toward Lake Kyoga and toward the Victoria Nile, where they ran up against the Acholi. To their south the Teso and the Kumam were also moving west and south. A flourishing trading network developed around Lake Kyoga.

Activity was rife also among the pastoral peoples to the east. In about 1850 the Turkana began to migrate from a base west of Lake Rudolf. Southward stood the Masai, the warrior people of the plains and open plateaus north and south of the string of Rift Valley lakes west of Mount Kenya. From 1830 onward their various subtribes were engaged, under the auspices of their rival *laibons,* or ritual leaders—among whom Mbatian, who succeeded his father, Subet, in 1866, was the most famous—in a succession of internecine conflicts largely over cattle and grazing grounds. Their wars denuded the Laikipia and Uasin Gishu plateaus of their former Masai, the so-called Wakwavi, who, being deprived of their cattle, switched to agriculture. They also helped the Nandi, who, with the Uasin Gishu Masai now troubling them no more, took to raiding on their own account from a base between the Rift Valley and Lake Victoria. Under the leadership of their *laibon*-like *orkoiyots,* the Nandi and their kinfolk, the Kipsikis, were soon the new powers in the land. Some of their neighbours who lived in open country put up defense works against them—the Baluyia, to the west, for exam-

The Masai wars

ple, built mud walls around their villages—while others, such as the Teita, the Kamba, and the Kikuyu, who lived on higher ground and in forest country, were rather better placed and from their carefully guarded fastnesses could defy the Masai. On the edges of their country they even entered into some permanent trade and marriage relations with the Masai. Where the soil was fertile, moreover, such people considerably increased their populations. Though they had no chiefs, "prominent men" were accorded a recognized status among them, and by the close of the century some of these were fighting each other for local supremacy.

Trade with the coast. On the coast, following the death, in 1856, of Sayyid Saʿīd, his erstwhile dominions in East Africa were split off from the imamate of Muscat. By 1873 the authority of the Āl Bū Saʿīdī sultans on Zanzibar itself became complete, although there were still revolts against them on the coast—particularly at Pate and Mombasa (where the Mazrui retained their preeminence despite successive defeats)—and at Kilwa, to the south. This arose chiefly from the sultan's acceptance of the further measures against the East African slave trade pressed upon him by the British consul at his court. By the 1860s some 7,000 or so slaves were being sold annually in the Zanzibar slave market, but in 1873 a treaty with the British closed the market at Zanzibar, and Sultan Barghash, by two proclamations in 1876, reduced the export from the mainland to a trickle. As it happened, however, there was then a final period of unprecedented slaving on the mainland, where the trade in slaves had generally been closely connected with the trade in ivory and the demand for porters was still considerable.

Trade in the East African interior began in African hands. In the southern regions Bisa, Yao, Fipa, and Nyamwezi traders were long active over a wide area. By the early 19th century Kamba traders had begun regularly to move northwestward between the Rift Valley and the sea. Indeed, it was Africans who usually arrived first to trade at the coast, rather than the Zanzibaris, who first moved inland. Zanzibari caravans had, however, begun to thrust inland before the end of the 18th century. Their main route thereafter struck immediately to the west and soon made Tabora their chief upcountry base. From there some traders went due west to Ujiji and across Lake Tanganyika to found, in the latter part of the 19th century, slave-based Arab states upon the Luapula and the upper reaches of the Congo. In these areas some of those who crossed the Nyasa–Tanganyika watershed (which was often approached from farther down the East African coast) were involved as well, while others went northwestward and captured the trade on the south and west sides of Lake Victoria. Here they were mostly kept out of Rwanda, but they were welcomed in both Buganda and Bunyoro and largely forestalled other traders who, after 1841, were thrusting up the Nile from Khartoum. They forestalled, too, the coastal traders moving inland from Mombasa, who seemed unable to establish themselves beyond Kilimanjaro on the south side of Lake Victoria. These Mombasa traders only captured the Kamba trade by first moving out beyond it to the west. By the 1880s, however, they were operating both in the Mount Kenya region and around Winam Bay and were even reaching north toward Lake Rudolf.

Zanzibari trade routes

The colonial era. Suggestions that he might at this time establish his dominion over the East African interior prompted Sultan Barghash to send a Baluchi force to Tabora, but the idea was never pursued. A comparable notion, however, led Khedive Ismāʿīl Pasha of Egypt to appoint in 1869 the Englishman Samuel White Baker as governor of the Equatorial Province of the Sudan, so that Baker might carry the Egyptian flag to the East African lakes. Though Baker reached as far south as Bunyoro in 1872, he was soon obliged to leave. His successor, Charles George Gordon, proposed to circumvent both Bunyoro and Buganda by going straight up the Nile's banks. But Mutesa I, kabaka of Buganda, frustrated Gordon's efforts on the Nile, and by the early 1880s, with bankruptcy in Egypt and the Mahdist revolt in the Sudan, only remnants of the Egyptian enterprise remained.

The Egyptian incursion had been the climax to the search by many European explorers for the headwaters of the Nile—a quest that had obsessed the later years of the Scottish missionary David Livingstone and had prompted the discovery in 1858 of Lake Tanganyika by the English expedition of Richard Burton and John Hanning Speke. Speke returned first to discover Lake Victoria in 1858 and then with James Grant in 1862 became the first white man to set eyes on the source of the Nile, which Speke named Ripon Falls. By circumnavigating Lake Victoria 12 years later, Henry Morton Stanley stilled the controversy that had ensued in Europe over Speke's claim.

Missionary activity. The revelations of these explorers, the example of David Livingstone, concern in western Europe over the East African slave trade, and the Roman Catholic and evangelical fervour that existed there inspired the invasion of the East African interior by a motley collection of Christian missionary enterprises. Johann Ludwig Krapf and Johannes Rebmann of the Church Missionary Society,who had worked inland from Mombasa and had, in the 1840s and '50s, journeyed to the foothills of Mount Kenya and Kilimanjaro, were followed by a British Methodist mission. Roman Catholic missionaries reached Zanzibar in 1860 and settled at Bagamoyo in 1868. An Anglo-Catholic mission first tried to establish itself in the Shire highlands, then in 1864 transferred to Zanzibar. Anglican missionaries arriving in Buganda in the mid-1870s at the request of Kabaka Mutesa were soon followed by Catholic White Fathers—there and elsewhere on Zanzibar's Tabora route—while the London Missionary Society sent men both to Unyamwezi and to Lake Tanganyika.

The Church Missionary Society

There were, of course, a number of localized religious movements among the peoples of East Africa during the 19th century. These included the Mbari cult among the Nyakyusa, the Nyabingi in Rwanda, and the Yakany movement north of Mount Ruwenzori. None of them, however, spread in quite the way that the Chwezi movement had earlier. Islām, on the other hand—spread widely at the instance of the Zanzibari traders and long established on the coast—had secured a scattering of converts in the interior as in the key kingdom of Buganda.

This was the scene onto which Christian missionaries first entered. Although by 1885 there were nearly 300 of them in East Africa, they did not initially win many converts, and those they at first obtained came only from among freed slaves and refugees from local wars. After 1880, however, they made important conversions in Buganda, and by the end of the century Christianity was spreading in the Lake Victoria area over most of the region in which the Chwezi movement had previously percolated—and before very long over a much larger area as well.

Partition by Germany and Britain. Philanthropic, commercial, and eventually imperialist ventures followed these evangelical endeavours. Nothing, however, of great moment occurred until 1885, when a German, Carl Peters, riding a tide of diplomatic hostility between Germany and Britain in Europe, secured the grant of an imperial charter for his German East Africa Company. With this, the European scramble for Africa began. In east-central Africa the key occurrence was the Anglo-German Agreement of 1886, by which the two parties agreed that their spheres of influence in East Africa should be divided by a line running from south of Mombasa, then north of Kilimanjaro to a point on the eastern shore of Lake Victoria. This began the extraordinary process by which the territories and subsequently the nations of East Africa were blocked out first upon the maps far away in Europe and only later upon the ground in East Africa itself.

THE HORN OF AFRICA

The history of the Horn of Africa has largely been dominated by Ethiopia and has been characterized by strug-

Struggle between Muslim herdsmen and Christian farmers

gles between Muslim and other herdsmen and Christian farmers for resources and living space. The Christians mostly spoke Semitic languages and the Muslims Cushitic tongues. Although these languages were derived from the same Afro-Asiatic stock, the more apparent differences between the peoples often were excuses for war, which, by the end of the 20th century, was waged under the banner of nationalism and Marxism-Leninism.

Aksum. When the Ethiopian empire of Aksum emerged into the light of history at the end of the 1st century AD, it was as a trading state known throughout the Red Sea region. Its people spoke Ge'ez, a Semitic language, and they mostly worshiped Middle Eastern gods, although here and there a traditional African deity survived. Its port of Adulis received a continuous stream of merchants who offered textiles, glassware, tools, precious jewelry, copper, iron, and steel in return for ivory, tortoiseshell, rhinoceros horn, gold, silver, slaves, frankincense, and myrrh. Aksum, the capital, was five days' march from the coast onto the Tigray Plateau, from which position it dominated trade routes into the south and west, where the commodities originated.

By the 4th century Aksum had become a regional power and an ally of Constantinople, whose language and culture attracted the ruling elites. Sometime around 321 Emperor Ezana and the Aksumite court converted to the monophysitic Christianity—a belief that Christ had one nature that was both divine and human—of Alexandria's See of St. Mark. During the next 200 years Christianity penetrated the masses, as foreign and native-born monks proselytized the interior, building churches and establishing monasteries wherever they found pagan temples and shrines.

Through the first half of the 6th century Aksum was the most important state in the Red Sea–Indian Ocean region and even extended its power over the kingdom of the Ḥimyarites on the Arabian Peninsula. In the Horn, Aksum dominated Welo, Tigray, Eritrea, and the important trade routes to and from the Sudan. The capital's stone buildings, monuments, churches, and 20,000 inhabitants were supported by tribute and taxes extracted from vassals and traders.

In 543 Abraha, the general in charge of Ḥimyar, rebelled and weakened Aksum's hold over South Arabia. This event marked the end of the empire's regional hegemony, allowed Persia to assume supremacy, and forced Constantinople into an overland trade route with India and Africa. Aksum's international trade diminished, a shift reflected in the debasement of the state's coins. The rise of Islām in Arabia a century later almost completely devastated Aksum, as Muslim sailors swept Ethiopian shipping from the sea-lanes.

Decline of Aksum

Aksum lost its economic vitality, and Adulis and other commercial centres withered. State revenues were greatly reduced, and the government could no longer maintain a standing army, a complex administration, and urban amenities. The culture associated with the outside world quickly became a memory, and Ethiopia learned to exist in local terms. The Christian state moved southward into the rich, grain-growing areas of the interior, where the rulers could sustain themselves. There, they and the local Cushitic-speaking population, the Agew, worked out a new political arrangement for Ethiopia.

The Somali. Meanwhile, another Cushitic people, the Somali, had separated themselves from the Oromo in what is now north-central Kenya. For their livelihood, they depended upon the one-humped Arabian camel, sheep, and goats. During the first centuries AD they migrated in a southeastern direction, finally following the Tana River to the Indian Ocean. They then turned north and peopled the entire Somali peninsula, coming into contact on the coast with Arab and Persian trading communities, from whom they took Islām and a mythological Arabian origin. By the 12th century the entire northern Somali coast was Islāmized, providing a basis for proselytism in the interior. But, as the Somali migration and Islām moved westward, they encountered a resurgent Christian Ethiopia.

The Solomonids. An amalgamated Christian state, led by Semitized Agew, had reappeared in the 12th century. This Zagwe dynasty gave way in the late 13th century to a dynasty that claimed descent from King Solomon and the Queen of Sheba, a genealogy providing the legitimacy and continuity so honoured in Ethiopia's subsequent national history. During the 14th and 15th centuries the Solomonid monarchs expanded their state southward and eastward. By then Muslims dominated Ethiopia's trade, which exited via Mitsiwa in Eritrea or through Seylac on the northern Somali coast.

The Solomonids permitted Muslim business activities in return for submission and taxes. In 1332 Ifat, a large Muslim polity with its port at Seylac, fed up with being a Christian vassal, declared a holy war against Ethiopia and invaded its territory, destroying churches and forcing conversions to Islām. The Ethiopian emperor, Amda Tseyon, fought back hard, routed the enemy, and carried the frontier of Christian power to the edge of the Shewan Plateau, overlooking the largely Muslim-inhabited Awash valley. One hundred years later, under Emperor Zara Yakob, the Solomonid empire extended its authority southward to modern Bale and Sidamo.

By then Ethiopia faced a challenge from Adal, Ifat's militant successor. Located in the semidesert Hərər region, Adal employed highly mobile Somali and Afar cavalry, whose raiding Ethiopia could not control. Meanwhile, the Solomonid state had begun to decay, owing to succession problems and the sheer complexity of governing a large empire. The Muslims consequently stopped paying tribute and a percentage of their trading profits to the hated Christians. Thereafter, they grew stronger and more daring, responding in part to overpopulation among the Somali.

Aḥmad Grāñ

The distress was exploited by the charismatic Aḥmad ibn Ibrāhīm al-Ghāzī, known to the Ethiopians as Aḥmad Grāñ ("Aḥmad the Left-handed"). A pious, indeed rigorous, Muslim, Aḥmad railed against the secular nature of Adal, mobilized tribesmen to purify the state, and trained his enlistees to use the modern tactics and firearms recently introduced by the Ottomans into the Red Sea region. After he took over Adal about 1526, his refusal to pay tribute triggered a Solomonid invasion in 1527, which his army easily repulsed.

Aḥmad thereupon declared a holy war, led his men into Ethiopia, and won battle after battle, fragmenting the Solomonid state into its component parts. During 1531–32 the Muslims pushed northward, traversing the rich Amhara Plateau north of the Awash and destroying churches and monasteries. Aḥmad Grāñ built a civil administration composed of his own men, remnants of the pre-Solomonid ruling classes, and collaborators. By 1535 he headed a vast Islāmic empire stretching from Seylac to Mitsiwa on the coast and including much of the Ethiopian interior, but not the staunchly Christian mountain fastnesses.

There, in 1541, Emperor Galawdewos learned that 400 Portuguese musketeers had disembarked at Mitsiwa in response to pleas for assistance. Though they lost half their strength moving inland, their weapons and tactics inspired Galawdewos to exploit Ethiopia's difficult terrain by undertaking hit-and-run warfare. Aḥmad never knew where his adversaries would strike and therefore placed his forces in defensive positions, where they lost their mobility, while he and his personal guard acted as a rapidly deployed reserve. Encamped at Weyna Dega near Lake Tana, Aḥmad's unit was attacked on Feb. 21, 1543, by Galawdewos and a flying column. During the hard-fought battle Aḥmad was killed, and that single death ended the war.

Christian Ethiopia was reprieved, but at a great cost. The country had lost hundreds of thousands of lives, confidence in itself and its religion, and its store of capital. Unable to follow Europe into commercial and then industrial capitalism, Ethiopia rebuilt feudalism, because the state simply had to restore affordable administration. By the early 1550s Galawdewos had fashioned a reasonable facsimile of the high Solomonid empire. Muslims, especially in the border provinces of Ifat, Dawaro (in the modern Arsi region), and Bale, remained disaffected. Christian converts along the periphery of the heartland, south of the Blue Nile and the Awash River, chafed under

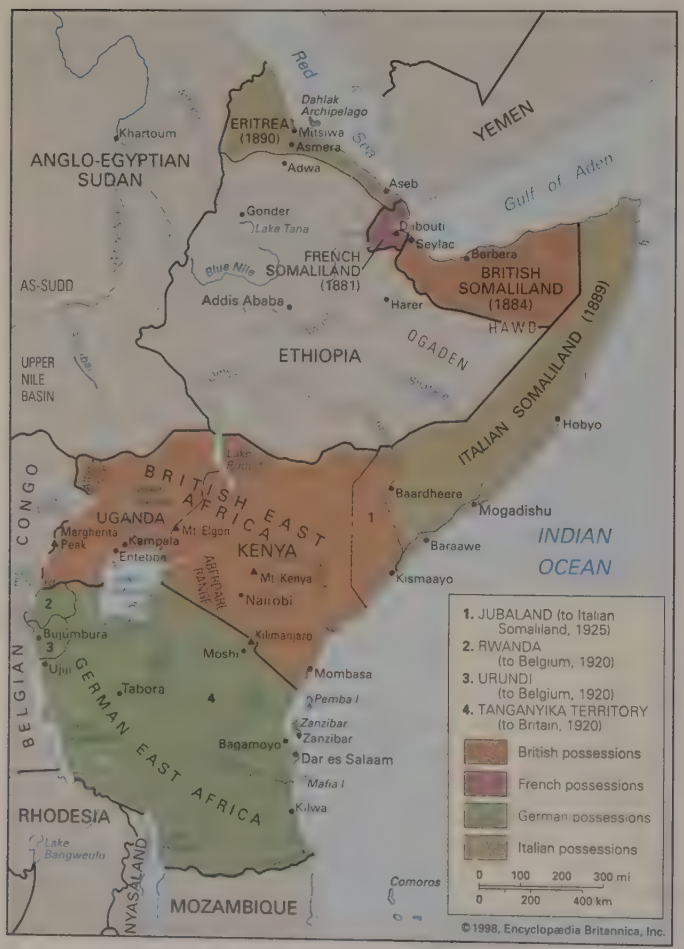
renewed exploitation, and the Judaized Falasha, to the north of Lake Tana, returned to their life of dispossession and economic marginalization. Finally, south of Lake Tana, in modern Gojam, Welega, Ilubabor, Kefa, Gamo Gofa, and Sidamo, a whole range of people remained tributary to the Christian kingdom. From among this last category emerged a new and more fundamental threat to old-fashioned Ethiopia.

Peoples tributary to the Ethiopians

Rise of the Oromo. The challenge came from the Oromo, a Cushitic-speaking pastoralist people whose original homeland was located on the Sidamo-Borena plain. From there, the related Afar and Somali peoples had hived off northeastward to the Red Sea coast, the Indian Ocean, and the Gulf of Aden, perhaps in some way causing the pressures that finally erupted in Aḥmad Grāñ's invasion of the Solomonid state. Some Oromo may have climbed onto the high Christian plateaus as early as the late 13th century, only to be repulsed. Garrisons established along the empire's periphery by Amda Tseyon and Zara Yakob were designed to keep the Oromo out, but when these defenses were destroyed during the war with Aḥmad Grāñ, the Oromo naturally resumed infiltrating.

The Oromo had an age-set form of government that changed every eight years, when a new warrior class sought its fortune by raiding and rustling in order to provide resources that the natural environment lacked. Every eight years, from the 1540s on, they advanced farther into the well-watered, fertile highlands—a sharp contrast with their arid bush country. Helped by their adversary's warweariness, demoralization, and depopulation, the Oromo invariably won territory after territory. By the beginning of the 17th century they had pushed northwestward into the modern regions of Arsi, Shewa, Welega, and Gojam and northeastward into Harerge and Welo, stopping only where they were blocked by forest, high population density, or effective mobilization of Christian forces.

Abyssinia. The Christians retreated into what may be called Abyssinia, an easily defensible, socially cohesive unit that included mostly Christian, Semitic-speaking peoples in a territory comprising most of Eritrea, Tigray, and Gonder and parts of Gojam, Shewa, and Welo. For the next two centuries Abyssinia defined the limits of Ethiopia's extent, but not its reach, for the Christian highlands received the hinterland's trade in transit to the Red Sea and the Nile valley. A complex caravan network linked Mitsiwa (now Massawa, Eritrea) on the Red Sea coast with the highlands of the interior. Gonder, the new capital, became a regional centre, doing business with the Sudanese cities of Sannār and Fazughli for slaves and gold, bought and paid for with coffee obtained from the Oromo-dominated lands. Demand for Ethiopian products increased considerably during the last quarter of the 17th century, as Yemen, a major trading partner on the Arabian Peninsula, sought increasing amounts of coffee for transshipment to Europe.



Eastern Africa as partitioned by the imperial powers, *c.* 1914.

Revival of the Ethiopian empire. By the late 19th century the northernmost Oromo had been assimilated into Christian culture, and Abyssinia's national unity had been restored after a century of feudal anarchy that ended with the accession of Yohannes IV in 1872. Yohannes forced the submission of Ethiopia's princes, repulsed Egyptian expansionism in 1875–76, pushed back Mahdist invasions in 1885–86, and limited the Italians to the Eritrean coast. Meanwhile, the ambitious King Menilek II of Shewa began a reconquest of Ethiopia's southern and eastern peripheries in order to acquire commodities to sell for the weapons and ammunition he would need in his fight for the Solomonid crown. Italian adventurers, scientists, and missionaries helped organize a route, outside imperial control, that took Shewan caravans to the coast, where Menilek's ivory, gold, hides, and furs could be sold for a sizable (and untaxed) profit.

The rise of Menilek

The economy of the Red Sea region had been stimulated by the opening of the Suez Canal, by the establishment of a British base in Aden, and by the opening of a French coaling station at Obock on the Afar coast. Britain sought to close off the Nile valley to the French by facilitating Rome's aspirations in the Horn. Thus, after 1885, Italy occupied coastal positions in Ethiopia and in southern Somalia. This limited the French to their mini-colony, leaving the British in control of ports in northern Somalia from which foodstuffs were exported to Aden. After Yohannes' death in March 1889, the Italians hoped to translate a cordial relationship with the new emperor, Menilek, into an Ethiopian empire.

On May 2, 1889, Menilek signed at Wichale (known as Ucciali to the Italians) a treaty of peace and amity with Italy. The Italians' famous mistranslation of Article XVII of the Treaty of Wichale provided them with an excuse to declare Ethiopia a protectorate. To Italy's dismay, the new emperor promptly wrote to the Great Powers, rejecting Rome's claim. Since neither France nor Russia accepted the new protectorate status, Ethiopia continued to acquire modern weapons from these countries through Obock. When, by 1894–95, Italy not only refused to rescind its declaration but also reinforced its army in Eritrea and invaded eastern Tigray, Menilek mobilized.

In late February 1896 an Ethiopian army of approximately 100,000 men was encamped at Adwa in Tigray, facing a much smaller enemy force some miles away. The Italians nevertheless attacked and were defeated on March 1, 1896, in what became known to Europeans as the Battle of Adowa (Adwa). Menilek immediately withdrew his hungry army southward with 1,800 prisoner-hostages, leaving Eritrea to Rome in the hope that peace with honour would be restored quickly. On Oct. 26, 1896, Italy signed the Treaty of Addis Ababa, conceding the unconditional abrogation of the Treaty of Wichale and recognizing Ethiopia's sovereign independence.

During the next decade, Menilek directed Ethiopia's return into the southern and western regions that had been abandoned in the 17th century. Most of the newly incorporated peoples there lived in segmented societies, practiced animal husbandry or cultivation with digging stick or hoe, followed traditional religions or Islām, and spoke non-Semitic languages. In practically every way but

Conquest of tributary peoples

skin colour, the northerners were aliens. Their superior weapons and more complex social organization gave them a material advantage, but they also were inspired by the idea that they were regaining lands that had once been part of the Christian state. Menilek and his soldiers believed that they were on a holy crusade to restore Ethiopia to its historic grandeur, but they did not realize that they were participating in Europe's "scramble for Africa" and that they were creating problems among nationalities that would afflict the Horn of Africa throughout the 20th century.

The birth of Somali nationalism. About 1900 the first of these problems erupted in Somali-inhabited regions, under the leadership of Sayyid Maxamed Cabdulle Xasan. The rebellion was directed at the British, Italians, and Ethiopians, whom Maxamed regarded equally as oppressors and infidels. Indeed, these powers admitted their collusion by collaborating militarily against the sayyid and his forces from 1901 to 1904, forcing him to sue for peace and to withdraw into a remote and unadministered area of Italian Somaliland. By 1908 he was again on the attack, this time causing a massive civil war, during which tens of thousands of Somali clansmen died. The Italians and the British chose not to intervene, preferring to let Somali kill Somali, and limited their activities to the coast. It was not until 1920 that British air power ran the sayyid to ground, forcing him to flee into the Ogaden, where he died on Dec. 21, 1920.

Maxamed pioneered the traditions of modern Somali nationalism, which combined Islām and anti-imperialism in a movement that sought to transcend clan divisions and make all Somali aware that they shared a common language, religion, way of life, and destiny. The Somali were further informed about their potential unity by, ironically, their Italian colonizers.

Italian rule. Despite the defeat at Adwa, Rome had not abandoned its dream of an Ethiopian empire. To this end, it worked hard at economic penetration but was invariably frustrated. More successful was its infiltration from Somalia into the adjacent Ogaden, where colonial troops seized strategic wells and posed as the protectors of Islām and the Somali people. By 1932 this advance alarmed Emperor Haile Selassie I, who was building a modern state in order to safeguard Ethiopia's independence.

Haile Selassie I

As regent to Empress Zauditu from 1916 to 1930, and afterward as monarch, Haile Selassie had worked to reform the economy, government, communications, and military. His success was recognized early, on Sept. 28, 1923, when Ethiopia entered the League of Nations. These achievements presaged a modern Ethiopian state that would block Rome's colonial plans and perhaps even undermine its position in the Horn of Africa. The potential threat of such a state, as well as considerations of European politics, led to the Italo-Ethiopian War, which began in the Ogaden, in December 1934, with a confrontation between Italian and Ethiopian soldiers at the water holes of Welwel.

Rome used Somalia and Eritrea as bases from which to launch its attack in October 1935. The issue was never in doubt; Haile Selassie had neither the armaments nor the disciplined troops necessary to fight the modern war that Italy mounted. In May 1936, after a terrible war that featured aerial bombardment and poison gas, he went into exile, and Italy proclaimed an East African empire consisting of Ethiopia, Eritrea, and its colony of Somalia.

The new regime, ignoring Ethiopia's traditional political organization, enlarged Eritrea to incorporate most of Tigray and placed the Ogaden in Somalia. In August 1940, after Rome had declared war against the Allies, the Italians marched north and occupied British Somaliland for seven months until dislodged by an Anglo-Ethiopian victory in the Horn of Africa. In 1942 and 1944 Anglo-Ethiopian treaties left the Ogaden under British rule for the duration of World War II, although Addis Ababa's sovereignty over the region was acknowledged. The British governed both Somalilands from a single city, Berbera, continuing the unification of the two territories.

Pan-Somalism. The Italians left Somaliland with an administrative infrastructure, communications, and towns, and the southern centres became incubators of pan-Somali ideas, which were quickly transmitted to their northern compatriots. The British allowed their subjects relative political freedom, and on May 13, 1943, the Somali Youth Club was formed in Mogadishu. Devoted to a concept of Somali unity that transcended ethnic considerations, the club quickly enrolled religious leaders, the gendarmerie, and the junior administration. By 1947, when it became the Somali Youth League, most of Somaliland's intelligentsia was devoted to pan-Somalism. This view was echoed in the British government's idea of Greater Somalia—a notion that was anathema to Ethiopia.

After his return to Addis Ababa in May 1941, Haile Selassie worked consistently to restore Ethiopia's sovereignty and to fend off British colonial encirclement and the isolation of his state. He regarded British activities in Somaliland as subversive and turned to the United States, which he concluded would be the dominant postwar power, to balance the geopolitical threat. American lend-lease and other assistance permitted Ethiopia to rebuff Britain and to secure the return of the Ogaden in 1948. The vision of Greater Somaliland, however, dominated Somali political programs in subsequent years.

The Ogaden returned to Ethiopia

Eritrean nationalism. Another fixed idea, that of Eritrean independence, also derived from the Italian years. Partisans here argued that Eritrea had evolved modern social and economic patterns and expectations from its colonial experience and, between 1941 and 1952, from the political freedoms allowed by the relatively liberal British military administration. While some Eritreans, especially Muslims and intellectuals, held these views in the 1940s, the idea of union with Ethiopia attracted the largely Christian population in the highlands—arguably the colony's majority. The Christians joined the Unionist Party, sponsored by the Ethiopian government, which simultaneously sought international support for regaining its coastal province. The Ethiopians were assisted by an international fact-finding commission that visited Eritrea in late 1948 and concluded that there was no national consciousness to nourish statehood and that its backward agriculture, crude industrial base, and poor natural resources would not sustain independence. The commission recommended some form of dependency—a decision ultimately referred to the United Nations, where the United States was the most influential power.

Washington was concerned about retaining control of a communications station near the Eritrean city of Asmera (now Asmara), which beamed intelligence information from the Middle East to the Pentagon, and it decided to support Ethiopia's claim to Eritrea in return for a formal base treaty. With U.S. leadership, the United Nations agreed to a federation of Ethiopia and Eritrea, which came into being in 1952. One year later, responding to growing Soviet influence in Egypt, Washington decided to provide Ethiopia military and economic aid. The United States subsequently became Ethiopia's main supplier of capital, expertise, and technology as well as military training, equipment, and munitions—a relationship that ultimately drove Somalia into an alliance with the Soviet Union.

Somalia irredenta. The Mogadishu government became independent on July 1, 1960. Its flag was dominated by a star, three points of which represented Djibouti, the Somali-inhabited northern region of Kenya, and the Ethiopian Ogaden. Together, these made up Somalia irredenta. In the Ogaden, young men organized themselves into clandestine fighting units, heeding Mogadishu's constant radio broadcasts to prepare for a war of liberation. In February 1963, the Ethiopian government sought to introduce a head tax to help sustain development efforts in the Ogaden. Somali nomads vigorously resisted the tax and rebelled, supported by the armed bands and then, in the fall of 1963, by Somalian troops. In November Mogadishu signed a military assistance pact with the Soviet Union, which undertook to equip a 20,000-man army. Shocked, the Ethiopians attacked Somalian border posts and adjacent towns in January 1964 and, after hard fighting, forced a cease-fire. Subsequent negotiations, however, were unable to resolve the differences between Somalia's goal of uniting all its compatriots and Ethiopia's need to retain its national integrity—as it was doing in Eritrea.

Efforts to absorb Eritrea

Cracks in the empire. From the Ethiopian federation's very inception, the imperial government had worked to transform Eritrea into an ordinary province. Courts, schools, and social services slowly became organs of the imperial regime; freedoms enunciated in the Eritrean constitution were suborned; political parties were suppressed; leading personalities were exiled; use of the Amharic language and other attributes of imperial culture were imposed on the population; the Eritrean flag was banned; and in 1960 the designation Eritrean government was changed to Eritrean administration. Furthermore, though Eritrea had received more development funds than any other region in Ethiopia, its towns and industries once sustained by the needs of the Italian colonial and British military regimes had difficulty competing in a national economy.

In July 1960 a group of mostly Muslim exiles in Cairo announced the establishment of the Eritrean Liberation Front (ELF). Its manifesto, which called for armed struggle to obtain Eritrea's rights, attracted the support of Syria, which eagerly offered military training for rebellion in a country tied to the United States and Israel. This largely Muslim movement received an infusion of young Christians after 1962, when, through Addis Ababa's manipulation, the Eritrean assembly voted to adopt the status of a governorate. The ELF now had sufficient strength to attack Eritrea's administrative and economic infrastructure. In December 1970 the imperial government declared a state of emergency in parts of Eritrea and stepped up counterinsurgency activities.

The government also used force in Bale and Sidamo between 1963 and 1970, putting down a rebellion among Oromo farmers and Somali herders against new land and animal taxes. This inevitably became involved with the politics of Somalia irredenta. By late 1966 rebels controlled both southern Bale and southeastern Sidamo and, at the same time, were attacking northern districts at will. It was not until the government sent in two army brigades and several squadrons of ground-attack jets that the rebellion was suppressed.

The Ethiopian government had proved unable to undertake the social and economic programs that could win the allegiance of the people. Force became the only tool of social control, partly because the emperor had grown reliant on the military but also because his government was inherently weak. For students in Addis Ababa, Haile Selassie was an agent of reaction, and his supporters were seen as exploiting Ethiopia for the benefit of the United States and its allies. They identified the monarchy and the ruling elites as the enemy of the people, pointing to the huge profits they made from sharecropping and other forms of capitalistic agriculture. Indeed, radiating from Addis Ababa was a zone of economic development that grew annually, dislocating traditional farmers. Peasant anxieties about land dispossession were loudly repeated by the students, who abhorred the realities of unequal economic growth and opted instead for the theoretical egalitarianism of unproved Marxist-Leninist models of development.

Problems in the countryside

Militarism in the Horn. Meanwhile, the Soviets were busily arming Somalia, which by 1970 had become the most militarized state per capita in the Horn of Africa, sustaining 20,000 troops. Ethiopia's armed forces remained between 45,000 and 50,000, with the portion of government expenditure devoted to the military actually declining from about 20 percent in 1970 to 14 percent by 1974. Addis Ababa thus managed to contain the Eritrean guerrillas and to keep the Somali in check with relatively modest outlays and was able to devote more of its resources to economic development programs. The imperial regime may have wanted to spend more on the military, but its chief arms supplier, the United States, had long before decided not to permit Ethiopia an offensive capability and therefore provided money and arms only for internal security and for frontier defense.

Rise of the Derg. By 1973 it was clear that the power behind the Ethiopian throne was the army. In early 1974 the government was unable or unwilling to respond to economic crises caused by the inflation of petroleum prices and by drought and famine in northern Ethiopia. When junior officers and other ranks went on strike over working conditions and inadequate supplies and equipment, the government resigned. Although a new cabinet was appointed, dissidents within the military organized into a central committee, called the Derg. This quickly became the real government as the emperor's men dissipated their energies in coping with a series of demonstrations.

Simultaneously, the army was being infused with fully developed Marxist-Leninist ideas by homegrown ideologues or by returnees from Europe and America. The Western dogma was swallowed whole by the more militant and socially conscious officers and men, whose agenda quickly became the abolition of the monarchy and the creation of a socialist state. On Sept. 12, 1974, Haile Selassie was deposed and, during the next year, most industry and all land were nationalized, new mass organizations were put in place, and programs were begun that could not be implemented effectively because the soldiers always sought a military solution to political problems. The situation in Eritrea therefore continued to deteriorate, and the west was abandoned to the insurgents, now dominated by the more secular Eritrean People's Liberation Front (EPLF). The EPLF took most of eastern Eritrea, leaving only the major centres in government hands.

Eritrean rebel groups

War in the Ogaden. In Addis Ababa, meanwhile, civilian opposition to the military government erupted in urban civil war. On Feb. 11, 1977, Mengistu Haile Mariam was named head of state and chairman of the ruling military council, and throughout 1977 anarchy reigned in the country as the military suppressed its civilian opponents. During this trauma the Somali chose to attack.

The Somalian president, Maxamed Siyaad Barre, was able to muster 35,000 regulars and 15,000 fighters of the Western Somali Liberation Front (WSLF). His forces began infiltrating into the Ogaden in May–June 1977, and overt warfare began in July. By September 1977 Mogadishu controlled 90 percent of the Ogaden and had followed retreating Ethiopian forces into non-Somali regions of Harerge, Bale, and Sidamo.

After watching Ethiopian events in 1975–76, the Soviet Union concluded that the revolution would lead to the establishment of an authentic Marxist-Leninist state and that, for geopolitical purposes, it was wise to transfer Soviet interests to Ethiopia. To this end, Moscow secretly promised the Derg military aid on condition that it renounce the alliance with the United States. Mengistu, believing that the Soviet Union's revolutionary history of national reconstruction was in keeping with Ethiopia's political goals, closed down the U.S. military mission and the communications centre in April 1977. In September, Moscow suspended all military aid to the aggressor, began openly to deliver weapons to Addis Ababa, and reassigned military advisers from Somalia to Ethiopia. This Soviet volte-face also gained Ethiopia important support from North Korea, which trained a People's Militia, and from Cuba and the People's Democratic Republic of Yemen, which provided infantry, pilots, and armoured units. By March 1978, Ethiopia and its allies regained control over the Ogaden.

Fall of military governments. Mengistu's government was unable to resolve the Eritrean problem, however, and expended large amounts of wealth and manpower on the conflict while rebellion spread to other parts of Ethiopia. Similarly, Siyaad proved unable to return the Ogaden to Somalian rule, and the people grew restive; in northern Somalia, rebels destroyed administrative centres and took over major towns. Both Ethiopia and Somalia had followed ruinous socialist policies of economic development, and they were unable to surmount droughts and famines that afflicted the Horn during the 1980s. In 1988 Siyaad and Mengistu agreed to withdraw their armies from possible confrontation in the Ogaden.

By 1989 Siyaad had refused serious political negotiations with his opponents, and fighting in Somalia spread southward and to Mogadishu. Amid increasing anarchy, the president fled in 1991, leaving Somalia to disintegrate into clan units.

Meanwhile, Mengistu refused to negotiate provincial autonomy, sparking the growth of ethnically based organizations. By 1987 the Tigre People's Liberation Front

(TPLF) controlled much of Tigray province. After a failed military coup in 1989, the TPLF advanced toward Shewa, attracting supporters from other areas. The TPLF joined with other forces to form the Ethiopian People's Revolutionary Democratic Front (EPRDF), which, with the EPLF, defeated Mengistu's forces throughout 1990 and 1991. Mengistu fled in May 1991, and the EPRDF began organizing an ethnically based government. The EPLF declared itself the de facto government of Eritrea and made moves toward independence. The intense upheaval, destitution, and fragmentation in the Horn of Africa put into question the future of political and territorial alignments.

THE COUNTRIES OF EAST AFRICA

Kenya

The Republic of Kenya (in Swahili, Jamhuri ya Kenya), a member of the Commonwealth of Nations, is one of the most strategically located countries of eastern Africa. Bisected horizontally by the equator and vertically by the 38th meridian (east), it is bordered on the north by Ethiopia and The Sudan, on the west by Uganda and Lake Victoria, on the south by Tanzania, and on the east by the Indian Ocean and Somalia. Kenya has an area of 224,961 square miles (582,646 square kilometres).

Diversity and unity

Kenya's present boundaries, the product of rivalries between colonial European powers, contain a number of ethnically diverse peoples who are independent and proud of their cultural heritage. Yet Kenyans are also acutely aware of the need to forge a strong national identity, of which cooperation is a basic ingredient. Since independence in 1963, the government has rallied the people under a national motto of "Harambee," or "Pulling together." Postcolonial development has been a mixture of pragmatic economic policy and of communal effort based on the principle of self-help. In this way the republic has tried to strengthen its traditional agricultural base as a foundation for industrialization. In addition, it continues to promote tourism, for the beauty and variety of Kenya's landscape, the pleasant and sunny climate, and the impressive dances and music of the Kenyan people are among the sure foundations that attract a growing stream of tourists to the country.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The 38th meridian divides Kenya into two halves of striking diversity. While the eastern half slopes gently to the coral-backed seashore, the western portion rises more abruptly through a series of hills and plateaus to the Eastern Rift Valley, known in Kenya as the Central Rift. West of the Rift is a westward-sloping plateau, the lowest part of which is occupied by Lake Victoria. Within this basic division, Kenya is divided into the following geographic regions: the Lake Victoria basin, the Rift Valley and associated highlands, the eastern plateau forelands, the semiarid and arid areas of the north and south, and the coast.

The Lake Victoria basin is part of a plateau rising eastward from the lakeshore to the Central Rift highlands. The lower part, forming the lake basin proper, is itself a plateau area lying between 3,000 and 4,000 feet (900 and 1,200 metres) above sea level. The rolling grassland of this plateau is cut almost in half by the Kano Rift Valley, into which an arm of the lake known as Winam, or Kavirondo, Bay extends eastward for 50 miles (80 kilometres). The floor of the Kano Rift Valley, called the Kano Plain, merges north and south into highlands characterized by a number of extinct volcanoes. These include Mount Elgon, rising to 14,178 feet (4,321 metres) at the Ugandan border on the extreme north of the basin.

The Central Rift Valley splits the highlands region into two sections: the Mau Escarpment to the west and the Aberdare Range to the east. The valley itself is from 30 to 80 miles wide, and its floor rises from about 1,500 feet in the north around Lake Rudolf (in Kenya called Lake Turkana) to over 7,000 feet at Lake Naivasha but then drops to 2,000 feet at the Tanzanian border in the south. The floor of the rift is occupied by a chain of shallow lakes separated by extinct volcanoes. Lake Naivasha is the largest of these, the others including lakes Magadi, Nakuru, Bogoria, and Baringo. West of the valley, the diverse highland area runs from the thick lava block of the Mau Escarpment–Mount Tinderet complex northward to the Uasin Gishu Plateau. East of the Rift, the Aberdare Range rises to nearly 10,000 feet. The eastern highlands extend from the Ngong Hills and uplands bordering Tanzania northward to the Laikipia Plateau. Farther east they are linked by the Nyeri saddle to Mount Kenya, the country's highest peak, at 17,058 feet (5,199 metres). The relief of both highlands is complex and includes plains, deep valleys, and mountains. Important in the history and economic development of Kenya, the region was the focus of European settlement.

The Rift Valley highlands

The eastern plateau forelands, located just east of the Rift highlands, are a vast plateau of ancient rocks sloping gently to the coastal plain. They are a region of scattered hills and striking elevated formations, the most prominent being the Taita, Kasigau, Machakos, and Kitui hills. These hills form islands of more favourable climatic regimes and are surrounded by regions of greater aridity that make up the traditional famine areas.

The semiarid and arid areas in the north and northeast are part of a vast arid region extending from the Ugandan border to include Lake Rudolf and much of the plateau area between the Ethiopian and Kenyan highlands. (The area from Lake Magadi southward, though not as arid, shares the same characteristics.) There is scanty tree and grass cover here, but the areas of true desert are limited to the Chalbi Desert east of Lake Rudolf. The movement of people and livestock is strictly limited by the availability of water.

The coastal plain proper, which runs for about 250 miles along the Indian Ocean, is a narrow strip only about 10 miles wide in the south, but in the Tana River lowlands to the north it broadens to about 100 miles. Farther northeast, it merges into the lowlands of Somalia. The coast has excellent natural harbours, of which Mombasa is the best in East Africa.

Drainage. The major features of the drainage pattern of Kenya were created by the ancient crustal deformation of a great oval dome that arose in the west-central part of the country and created the Central Rift. This dome produced a primeval watershed from which rivers once drained eastward to the Indian Ocean and westward to the Congo system and the Atlantic Ocean. Still following this ancient pattern are the Tana and Galana rivers, which arise in the eastern highlands and flow roughly southeast to the Indian Ocean. West of the Central Rift, however, the major streams now drain into Lake Victoria. These include the Nzoia, Yala, Mara, and Nyando rivers. Between the eastern and western systems, the rifting of the dome's crust has created a complex pattern of internal streams that feed the major lakes.

Apart from the Tana River, most of the rivers of Kenya are short or ephemeral, disappearing in dry seasons. There are no major groundwater basins. Lake Victoria, extending over 26,828 square miles, is the largest lake in Africa and the second largest freshwater body in the world. Lake Rudolf, some 150 miles long and 20 miles wide, is the largest of the country's Rift Valley lakes. Other lakes are rather small and suffer large fluctuations in surface area.

Soils. In the Lake Victoria basin, lava deposits have produced fertile loam and sandy loam soils in the plateaus north and south of Winam Bay, while the volcanic pile of Mount Elgon is responsible for very fertile volcanic soils well-known for coffee and tea production. The

Fertile lava deposits

Central Rift Valley and associated highlands compose a distinct region of fertile, dark brown loams developed on younger volcanic deposits.

The most widespread soils in Kenya, however, are the sandy soils of the semiarid regions between the coast and the Rift highlands. To the north of the Rift are vast areas covered by red desert soils, mainly sandy loams. Because Kenya is very poorly forested, much of the soil is naturally exposed to widespread erosion. Erosion is stimulated as well by overgrazing and cultivation, especially in the arid and semiarid regions, and by encroachment of the limited forest areas.

Climate. Seasonal climatic changes are controlled by large-scale pressure systems of the western Indian Ocean and adjacent landmasses. From December to March, northeast winds predominate north of the equator and south to southeast winds south of the equator. These months are fairly dry, although rain may occur locally. The rainy season extends from late March to May, with air flowing from the east in both hemispheres. From June to August is a season of little rainfall in which southeast winds gradually prevail in the south and southwest winds blow north of the equator. October marks the beginning of a transition period ending with a return of the northeast and southeast winds.

In the Lake Victoria basin, mean annual rainfall varies from 40 inches (1,000 millimetres) around the lakeshore to well over 70 inches in the more elevated eastern areas. The lakeshore has excellent agricultural potential because it can expect 20 to 35 inches in 19 years out of 20. Daily maximum temperatures range from about 80° F (27° C) in July to 90° F (32° C) in October and February.

In the Central Rift Valley, mean annual temperatures decrease from about 84° F (29° C) in the north to just over 61° F (16° C) around Lakes Nakuru and Naivasha in the south. The bordering highlands are generally moderate, with mean annual temperatures ranging between 56° and 65° F (13° and 18° C). In general, the floor of the Rift Valley is dry, while the highland areas receive more than 30 inches of rain per year. In the Mau Escarpment, reliable rainfall and fertile soils form the basis of a thriving modern agriculture.

In most parts of the eastern plateau forelands, annual rainfall averages 20 to 30 inches, and agriculture is hampered by extremely uncertain rainfall. The semiarid and arid regions of northern, northeastern, and southern Kenya have very high temperatures and also suffer extremely erratic rainfall. Most places experience mean annual temperatures of 85° F (29° C) or more. Mean annual rainfall is only about 10 inches in the north and is less than 20 inches in the south.

The humid coast

Most parts of the coast experience mean annual temperatures in excess of 80° F (27° C) and high relative humidity year-round. From the humid coast, where mean annual rainfall is between 30 and 50 inches, precipitation decreases westward to about 20 inches per year. Only in the southern coast is rainfall reliable enough for prosperous agriculture.

Plant and animal life. In the highland area between 7,000 and 9,000 feet, the characteristic landscape consists of patches of evergreen forest separated by wide expanses of short grass. Where the forest has survived human encroachment, it includes economically valuable trees such as cedar (*Juniperus procera*) and podo wood (*Podocarpus milanjianus* and *P. gracilior*). Above the forest, a zone of bamboo extends to about 10,000 feet, beyond which there is mountain moorland bearing tree heaths, tree groundsel (a foundation timber of genus *Senecio*), and giant lobelia (a widely distributed herbaceous plant). East and west of the highlands, forests give way to low trees scattered through an even cover of short grass.

Semidesert regions below 3,000 feet give rise to baobab trees. In still drier areas of the north, desert scrub occurs, exposing the bare ground. The vegetation of the coastal region is basically savanna with patches of residual forests. While the northern coast still bears remnants of forests, years of human occupation in the south have virtually destroyed them.

Almost one-third of Kenya, particularly the western regions and the coastal belt, is infested with tsetse flies and mosquitoes. These insects are responsible for the prevalence of sleeping sickness and malaria in both the lake basin and the coastal region.

There is a close link between a region's vegetation and the differentiation and distribution of its wildlife. The highland rain forests support a variety of large wildlife dominated by elephant and rhinoceros, although these large animals have been much reduced by poaching and deforestation. Bushbuck, colobus monkeys, and occasional bushbabies are also found. In the bamboo zone are found varieties of the duiker. Predatory highland animals include lions, leopards, and wildcats. Birdlife is scanty.

The most prolific wildlife is found in the extensive grasslands between the forest zone and lower areas. The principal occupants here are varieties of ungulates, such as the hartebeest, wildebeest, zebra, and gazelle. Other members include waterbucks, impalas, elands, warthogs, and buffalo. Predators living on this grazing wildlife include the lion, spotted hyena, leopard, cheetah, and wild dog. Without the interference of the forest, birdlife is much richer here, and lakes and rivers are occasionally inhabited by hippopotamuses, crocodiles, and numerous fishes.

The coastal waters contain a wide variety of abundant fish life, including butterfly fish, angelfish, rock cods, barracuda, and spiny lobsters, while the coastal forest harbours suni antelopes, buffalo, and elephants.

In the thornbushes and thickets of the arid regions are elephants and rhinoceroses, lions and leopards, and giraffes, gerenuks, kudu, impalas, dik-diks, and lesser kudu. In the large rivers, hippopotamuses, crocodiles, and fishes may be found.

Traditional scattered settlements

Settlement patterns. Most of Kenya's population lives in scattered settlements, the location and concentration of which depend largely on climatic and soil conditions. Before colonization, virtually no villages or towns existed except along the coast, where pre-European urbanization was confined to fishing villages, Arab trading ports, and towns visited by dhows from the Arabian Peninsula and Asia. Mombasa, Lamu, and Malindi are among the few that expanded into modern towns. Other modern towns were established by Europeans at the coast and in the interior as administrative centres, mission stations, and markets.

Since independence, as urban areas have seen greater economic development, the migration from rural to urban areas has accelerated. In 1969 some 10 percent of the national population lived in urban areas of 1,000 or more people; by 1979 the urban population had grown to just under 15 percent. Along the coast, most of the urban population is found in the Mombasa complex, and in the interior the majority lives in the capital city of Nairobi.

The people. *Ethnicity, language, and religion.* The African peoples of Kenya, who account for about 98 percent of the total population, are divided into three main language groups. The largest of these is the Bantu group, which forms about two-thirds of the population and is largely concentrated in the southern third of the country. Bantu peoples occupying the fertile Central Rift highlands include the Kikuyu, Embu, Mbere, Kamba, and Tharaka. In the Lake Victoria basin they include the Luhya and Gusii.

The remainder of Kenyan Africans belong to the Nilotic and Cushitic language groups. The Nilotes, represented by the Luo, Kalenjin, Masai, and related peoples, make up about one-quarter of the total population. The rural Luo inhabit the lower parts of the western plateau draining into Lake Victoria, while the Kalenjin-speaking people occupy the higher parts of the plateau. The Masai are pastoral nomads in the southern region bordering Tanzania, and the related Turkana pursue the same occupation in the arid northwest.

The Cushitic-speaking peoples, who inhabit the arid and semiarid regions of the north and northeast, constitute only between 3 and 4 percent of Kenya's population. They are divided between the Somali, bordering Somalia, and the Oromo, bordering Ethiopia. The Cushitic peoples pursue a pastoral livelihood in areas that are subject to famine, drought, and desertification.

Apart from the African population, Kenya is home to various ethnic groups that immigrated during colonial rule from India and Pakistan. Referred to in Kenya as Asians, they are divided on the basis of religious affiliation into Hindus, Muslims, and Sikhs. Although many left after independence, a substantial number remain in urban areas such as Mombasa, Nairobi, and Kisumu.

European Kenyans, mostly British in origin, are the remnant of the farming and colonial population. At the time of independence, most Europeans emigrated to southern Africa, Europe, and elsewhere. Most of those remaining are to be found in the large urban centres of Nairobi and Mombasa.

Arabs (mostly the products of marriages between Arabs and Africans) live along the coast. Although all observe Islām, they are divided between the "old" Arabs, descended from Arabs who arrived before the 16th century, and the "true" Arabs, originating with the establishment of Arab hegemony in Zanzibar in the 19th century.

Swahili: the lingua franca

Although a wide variety of languages are spoken in Kenya, the lingua franca is Swahili. This multipurpose language, which evolved along the coast from elements of local Bantu languages, Arabic, Persian, Portuguese, Hindi, and English, is the language of local trade and is also used (along with English) as an official language in the National Assembly and the courts. In 1974 it became the official language, replacing English.

Kenya has no state religion. However, the majority of the Africans are members of the Roman Catholic, Anglican, and other Protestant churches. These religious affiliations are the outcome of early missionary activities, which assisted in the administrative pacification of the country during colonial times.

Population growth. In the late 20th century an accelerating population growth emerged as a serious constraint on social and economic development in Kenya. During the first quarter of the century, the total population was less than four million, and it was growing at a rate that would have doubled the population in 50 years. By the time of the 1948 census, the population had surpassed five million and was doubling every 30 years. By independence in 1963, the population had exceeded eight million and was doubling every 23 years, and by 1984 it had exceeded 19 million and the doubling time had been reduced to 18 years. The pressure of such a population explosion has been felt in limited employment opportunities, in the rising cost of education, health services, and food imports, and in the country's inability to generate the resources to build housing in both urban and rural areas.

The most important cause of this explosive growth has been a sharp fall in mortality rates—especially infant mortality—and a traditional preference for large families.

The economy. At the time of independence, Kenya's economy was characterized by a large traditional sector based on subsistence agriculture and the barter of goods, by a heavy dependence on foreign exchange for agricultural exports such as coffee and tea, and by a strong bond with the international economic system. Since 1963 the government has pursued a policy dedicated to a mixed economy of both privately owned and state-run enterprises. Most of Kenya's business is in private hands (with a great deal of investment by foreign firms), but the government also shapes the country's economic development through various regulatory powers and "parastatals," or enterprises that it partly or wholly owns.

The aim of this mixed economic policy has been to achieve economic growth and stability, to generate employment, and to maximize foreign earnings by maintaining the important agricultural exports while substituting domestically produced goods for goods that are traditionally imported. For a decade after independence, the policy showed great promise as rising wages, employment, and government revenue provided the means for expanding health services, education, and transportation and communication. But owing to setbacks, beginning with the rise of oil prices in 1973 and aggravated since then by periodic drought and accelerating population growth, Kenya's economy has proved unable to maintain a favourable balance of trade while addressing the problems of chronic poverty and growing unemployment.

Problems with economic growth

Agriculture. Although agriculture continues to dominate Kenya's economy, its share of the gross domestic product (GDP) declined from 42 percent in 1964 to 30 percent by 1987. Agriculture feeds the manufacturing sector with raw materials and supplies tax revenue and foreign exchange to support the rest of the economy.

Coffee and tea have continued to be the key foreign exchange earners. Other products that support external trade are pyrethrum, cotton, sisal, fruits, wattle bark, cashew nuts, and horticultural produce. For domestic consumption, the major farm products are corn (maize), potatoes, sugar, livestock, and poultry. Most of the country's livestock is raised in the arid regions by nomadic pastoral peoples who tend to keep them as a form of wealth rather than sell them for slaughter. Commercial stock raising is confined to small farms and large ranches, which raise animals for meat, hides, skins, and wool.

Despite the importance of agriculture to the economic well-being of the country, there are serious constraints on further expansion—in particular, the scarcity of water and the high cost of technological inputs.

Forestry. Although extremely important in the domestic economy, forestry is limited by the extent of forest land. Most of the total area of forest reserves is natural forest bush, bamboo, and grass; the remainder consists of planted softwoods, which now support a domestic paper industry. Forests are important in the conservation of Kenya's soil and water resources.

Fishing. Fish and other marine products represent a small but locally important portion of Kenya's natural resources. Freshwater fish from Lakes Victoria and Rudolf dominate fishery.

Mining. The mining industry is limited by the high cost of capital and by the limited market for Kenya's few mineral resources. Limestone deposits at the coast and in the interior are exploited for cement manufacture and agriculture. For the export trade, fluorite (used in metallurgy) is mined along the Kerio River in the north, and soda ash (used in glassmaking) is quarried at Lake Magadi.

Manufacturing. Manufacturing activity in Kenya is based on the processing of agricultural products, with agriculturally based industry accounting for about two-thirds of production. The country has a well-developed meat and meat-products industry and a thriving dairy industry. Production of sugar, textiles, paper, and leather has expanded greatly since independence. Exported agricultural products include processed fruits and extracts of pyrethrum (used in insecticides) and wattle bark (used in the tanning of leather).

Processing of agricultural products

Kenya's limited coal production supports several small steel-rolling mills. Petroleum products such as diesel and jet fuel, manufactured from imported crude at government-owned refineries near Mombasa, are important in

Cooperative workers drying coffee on racks, Nyeri, Kenya.

both domestic and export markets. Also, engineering industries assemble motor vehicles and machinery from imported parts, and components are made from imported raw materials. (S.H.O.)

Tourism. Kenya is home to some of the rarest and most interesting species of wildlife in the world. Because of this, tourism is one of the country's major sources of foreign exchange, with visitors coming largely from countries of the European Union. Tourism revolves around a basic framework of some 20 national parks, game reserves, and game sanctuaries, where a wide variety of animals and cultural attractions can be enjoyed. The number of tourists began to vary annually, however, following a period of political unrest and attacks on tourists in the early 1990s.

Energy. Kenya's economic development depends largely on the development of energy. The emphasis since independence has been on the production of hydroelectricity, but this has limitations as an energy source for rural Kenyans, since the bulk of electricity is consumed by the two major urban centres of Nairobi and Mombasa. The largest hydroelectric plants are on the Tana River, though the considerable potential of the Turkwel River in the northwest is also under development. Geothermal resources in the Central Rift Valley have also been tapped since the early 1980s to generate electricity and now supply a significant amount of Nairobi's total needs.

Wood fuel, primarily used for domestic cooking, is a vital part of the rural economy, but deforestation threatens the supply. A tree-planting program has been initiated to establish in ecologically suitable areas quick-maturing indigenous and exotic species for the supply of farm households.

Finance. The Central Bank of Kenya, established by legislation in 1966, regulates the money supply, assists in the development of the monetary, credit, and banking system, acts as banker and financial adviser to the government, and grants short-term or seasonal loans. There are also more than 20 operating commercial banks, with hundreds of branches, sub-branches, agencies, and mobile units, which offer savings deposits and checking accounts. Financial mismanagement and corruption led a number of institutions to bankruptcy in the 1990s.

Trade. Coffee and tea comprise about half of Kenya's exports. Other agricultural products constitute another fourth, and petroleum products make up most of the remainder. The countries of the European Union are the primary export destinations, with the United Kingdom and Germany leading the list. Imports include machinery and transport equipment, crude petroleum, fertilizers, chemicals and pharmaceuticals, and manufactured goods. The main suppliers are the United Kingdom, Saudi Arabia, Japan, Germany, and the United States.

Transportation. The development, both before and after independence, of its excellent transportation infrastructure has largely made possible the emergence of Kenya as a modern and viable state.

The road system

Kenya's roads, the major form of transport linking the urban areas with their rural hinterlands, were developed in colonial times as a subsidiary of the railway line running from Mombasa to the western parts of the country. After independence the heavily utilized trunk and primary roads were upgraded from dirt to bitumen and gravel. With the expansion of this network came a rapid increase in freight traffic carrying goods within Kenya as well as to Tanzania, Uganda, The Sudan, and Ethiopia. This has severely damaged Kenyan roads, necessitating heavy expenditure in repairs.

Railways, the second most important mode of transport after roads, are operated by Kenya Railways. The main line runs northwest from Mombasa through Nairobi, Nakuru, and Eldoret to the Ugandan border. Major branch lines run from Nakuru to Kisumu on Lake Victoria and from Nairobi to Nanyuki near Mount Kenya. Passenger services constitute only a tiny share of railway business.

The strategic location of Kenya on the western shores of the Indian Ocean, with easy connections to different parts of Africa and the world, has greatly enhanced the role of Kenya's two international airports at Nairobi and Mombasa. A third international airport, at Eldoret, was completed in 1996. Kenya Airways, established as a state-owned company in 1977, was privatized in 1996. There are domestic airports at Kisumu and Malindi.

Mombasa, the principal port of Kenya, handles the bulk of the import and export traffic of Kenya, Uganda, and the northern mainland of Tanzania. The ports of Lamu and Malindi serve mainly the coastal trade and fisheries.

Administration and social conditions. *Government.* Kenya reached independence on Dec. 12, 1963, under a constitution that placed the prime minister at the head of a cabinet chosen by a bicameral National Assembly. A great deal of power was granted to assemblies elected in each of the country's regions, and multiparty contests were allowed. Since independence a series of amendments has abolished the regional assemblies in favour of provincial commissions appointed by the national government, made the National Assembly a unicameral body, proclaimed the Kenya African National Union (KANU) the only legal political party, and replaced the prime minister with an executive president who has the power to dismiss at will the attorney general and senior judges. The effect of these changes has been to establish the central government—in particular, the presidency—as the principal locus of political power in the country, although multiparty politics was once again allowed in 1991. The constitution guarantees a number of rights such as the freedoms of speech, assembly, and worship, but it also allows the president to detain without trial persons who have been deemed a threat to public security.

Membership in a political party is a requirement for anybody seeking election or appointment to public office except the presidency. Several candidates from the party are often allowed to contest a single office, but any candidate who receives more than 70 percent of the votes in a nominating election goes through the final election unopposed.

The executive branch

The executive branch consists of the president and the cabinet ministers, all of whom are selected by the president from the National Assembly. The president is the head of state and commander in chief of the armed forces. He is elected by direct popular vote to a term of five years and must also be a member of the National Assembly. Through the cabinet, the president controls the passage of legislation as well as the huge bureaucracies directing the economy and provincial affairs. Cabinet ministers frequently change portfolios, leaving the administration of the ministries to civil servants.

The National Assembly varies from 202 to 224 members. Most are elected for five-year terms by universal adult suffrage, with 12 members appointed by the president and two ex officio members—the speaker and the attorney general, of whom only the speaker has voting privileges.

The judiciary is headed by the chief justice and 11 puisne, or associate, justices of the High Court, which has full civil and criminal jurisdiction and rules on constitutional matters. The Court of Appeal, consisting of the chief justice and several associates, is the highest appeals court in the land. At lower levels are resident magistrates' and district magistrates' courts. Kenya's judicial system acknowledges the validity of Islāmic law and indigenous African customs in many personal areas such as marriage, divorce, and matters affecting dependents.

Local government consists of appointed provincial and district commissioners, elected county, municipal, and town councils, and elected township or municipal authorities. The provincial commissioners are responsible for education, transport, and health in their provinces, while the councils are concerned with services and public works funded by local taxes and grants from the central government.

Education. A single national educational system consists of three educational levels. At the first are eight years of primary education. These are followed by four years of secondary education, and the third level is represented by four years of university education. When primary schooling is completed, entrance to the secondary level is contingent upon passing an examination.

Primary and secondary enrollment have expanded markedly with the growing population, severely straining the government's ability to provide occupational training

for the slower-growing job market. As accommodations in government-built secondary schools are limited, community-built *harambee* secondary schools were developed, but promised government assistance for these schools has not always materialized. Public universities include Nairobi, Kenyatta, Moi (formerly Eldoret), and Egerton universities as well as Jomo Kenyatta College of Agriculture and Technology.

Health. With support from the World Health Organization and other foreign donors, vaccination programs have wiped out or reduced the incidence of such infectious diseases as smallpox and measles. Together with improved housing, education, sanitation, and nutrition, health-care programs drastically reduced death rates (especially the infant death rate) and raised life expectancy. However, AIDS has become a major disease in Kenya, and the death rate has again climbed. Life expectancy has also dropped, averaging about 49 years. In addition, the continued high incidence of malaria, gastroenteritis, dysentery, trachoma, and schistosomiasis illustrates the difficulty of eradicating mosquitoes and providing clean water, especially in the countryside.

Kenyatta National Hospital in Nairobi is the chief referral and teaching institution, and there are also provincial and district hospitals. In rural areas, health centres and dispensaries offer diagnostic services, obstetric care, and outpatient treatment. Rural health services suffer from lack of facilities, trained personnel, and medications.

Cultural life. There is a marked contrast between urban and rural culture. The cities are characterized by a more cosmopolitan population whose tastes reflect practices that combine the local with the global. Nairobi's night life, for instance, caters to youth interested in music that varies from American rhythm and blues, rap, and rock music to Congolese forms of rumba.

Rural life is oriented in two directions—toward the lifestyles of rural inhabitants, who still constitute the majority of Kenya's population, and toward foreign tourists who come to visit the many national parks and reserves, which are perhaps Kenya's greatest cultural legacy.

The Kenya National Theatre is incorporated in the Kenya Cultural Centre. The National Theatre School was founded in 1968 to provide professional training in theatrical techniques, which include the writing of plays by Kenyan authors and the performance of traditional music and dance. Music and dance play an integral role in social and religious life. Rhythm, all-important, is largely provided by the drum, supplemented by wind and stringed instruments. Swahili literature, both oral and written, is traditional in form and content. Contemporary novelists, including Ngugi wa Thiong'o and Mugo Gatheru, deal with the social frictions between traditional and modern society. Visual arts are largely confined to the mass production of wood sculpture for the tourist trade. Elimo Njau and Ronal Rankin are popular Kenyan painters.

HISTORY

Control of the interior. The earliest recorded history of the area now known as Kenya concerns the coastline, which for centuries has had trading relations with southern Arabia. There is little reliable information about the interior in the period up to the 19th century. During the 19th century Arab and Swahili caravans in search of ivory penetrated from Mombasa to Kilimanjaro and thence to Lake Victoria and beyond toward Mount Elgon, but this route was not so popular as were the caravan trails farther south, both because of the difficulty in crossing the desert country of the Taru Plain and because of the hostility of the warlike Masai tribe. The first Europeans to penetrate into the interior were the German agents of the Church Missionary Society, Johann Ludwig Krapf and Johannes Rebmann, who established a mission station at Rabai, a short distance inland from Mombasa in the territory of the Manyika tribe. In 1848 Rebmann became the first European to see Kilimanjaro, and in 1849 Krapf ventured still farther inland and saw Mount Kenya. These were isolated journeys, however, and more than 30 years elapsed before any other Europeans attempted to explore the country dominated by the Masai.

The first Europeans

The Masai and Kikuyu. The pastoral Masai probably moved into what is now central Kenya from the north in the mid-18th century. Their southward advance was checked about 1830 by the Hehe of what is now Tanzania, but their raiding parties continued to range far and wide and even reached the coast south of Mombasa in 1859. Under the spiritual direction of the *laibon* ("medicine man"), the Masai were organized for war. Great power was placed in the hands of the *moran* ("warrior"), so that, although the Masai were not particularly numerous, they were able to dominate a considerable region and to terrorize their neighbours. Their chief victims were Bantu agriculturalists, who could offer little effective resistance to the unexpected raids of these nomadic people. The Nandi, who inhabited the escarpment to the west of the Masai, were equally warlike and remained relatively undisturbed by their predatory neighbours. On the eastern slopes of Kilimanjaro, the Taveta were able to take refuge in the forest, and, still farther east, the Teita used the natural strongholds provided by their mountainous homeland to resist the Masai raiders.

The Kikuyu, a much larger tribe and near neighbours of the Masai, also looked to the mountains and forests for protection against Masai war parties. The Kikuyu had expanded northward, westward, and southward from their territory in the Fort Hall area of present-day Central province, cutting down the forests to provide themselves with agricultural land. Toward the end of the 19th century, however, their advance had reached the limits imposed by the presence of the Masai to the north and south and by the upper slopes of the Aberdare Range to the west. To the south, in the region of Ngong, they were protected by a narrow belt of forest through which the Masai could penetrate only at risk of damage from traps and ambushes. The Kikuyu were organized in clans and by districts, and, although war leaders arose to help in the defense of the tribe against the Masai, the lack of a central form of government made them vulnerable to the raids of their neighbours.

In the 1890s famine and smallpox compelled the Kikuyu to withdraw northward, vacating much of the land in what is now Kiambu district. The Masai, too, were passing through a difficult period. An outbreak of disease, probably pleuropneumonia, had attacked their cattle in 1883, and in 1889–90 epidemics of rinderpest and smallpox further undermined their wealth and power. Simultaneously, the tribe was split on the death of its great *laibon,* Mbatian, and it was some time before his younger son, Lenana, was able to restore order. The legend of the Masai menace lingered on, but their power never revived, for their decline coincided with the arrival of European traders and administrators who took control of the country that the Masai had formerly ravaged but never ruled.

Decline of the Masai

The British East Africa Company. In 1883 Joseph Thomson, an explorer, became the first British traveler to pass through the Masai country, but it was the British East Africa Company that undertook the opening up of the land to the west of Mombasa. German interest in East Africa had resulted in November 1886 in the delimitation of the grandiose but inadequately authenticated territorial claims of the sultan of Zanzibar. After recognizing the sultan's authority over a 10-mile-wide coastal strip between the Ruvuma and Tana rivers, Germany, Britain, and France had agreed to divide the hinterland into British and German spheres of influence. The British took the area north of a line running from the mouth of the Umba River, opposite Pemba Island, and skirting north of Kilimanjaro to a point where latitude 1° S cuts the eastern shore of Lake Victoria. The German sphere was to the south of that line. In 1887 Sir William Mackinnon and the British East Africa Association (later Company) accepted a concession of the sultan's territory on the mainland for a 50-year period, subsequently amended to a grant in perpetuity. The British government, reluctant to become involved in the

administration of East Africa, agreed in 1888 to a petition from the association asking for a charter of incorporation authorizing the acceptance of existing and future grants and concessions for the administration and development of the British sphere.

The financial resources of the new Imperial British East Africa Company were scarcely adequate for any large-scale development of East Africa. Becoming involved in civil war in Uganda, the company soon found itself unable to maintain its high level of expenditure and was forced to limit its activities to the region nearer the coast. In 1894 the British government declared a protectorate over Buganda and, in the following year, in order that it might itself guard the line of communication between the coast and Buganda, called upon the company to surrender its charter and concession in return for £250,000 compensation. The East Africa Protectorate was then proclaimed, and Sir Arthur Hardinge became the first commissioner. The lack of importance attached to the new protectorate by the British government was indicated by the fact that Hardinge continued to maintain his headquarters in Zanzibar, where he already fulfilled the duties of consul general.

Opposition to colonial rule

The East Africa Protectorate. The early years of the new administration were largely taken up in asserting its authority over tribes that did not understand the change that had taken place. This could scarcely be said of the chiefs of the Mazrui family along the coast, who actively resisted the usurpation of their authority by the British administrators. The Kikuyu and the Kamba, however, simply opposed what appeared to them to be an unwarranted invasion of their territory, and in 1896 and 1897 small military expeditions had to be sent against them by the new administration. Farther west the Nandi did not accept their new overlords until 1905, after a series of military columns had ranged through their territory with varying success. The Masai alone among the more important tribes offered no resistance to British authority.

The lack of communication and the limited financial resources available locally or granted by an apathetic British government meant that orderly administration was only slowly extended into the more remote areas of the protectorate. The absence of any strong indigenous forms of political organization that might have been employed as agents of the new protectorate also delayed progress. The introduction of direct rule through the agency of European administrative officers was not, therefore, so much a question of policy as a matter of necessity.

The Uganda railway and European settlement. At the beginning of the 20th century, the importance of the East Africa Protectorate was thought to lie in its value as a corridor to the fertile country around Lake Victoria. This view was further strengthened by the fact that the Kedong River marked the western boundary of the protectorate, so that the fine highland pastures to the west of the Rift Valley still formed part of the Uganda protectorate. Consequently, although regulations were issued in 1897 authorizing the lease to Europeans of land that was not cultivated or regularly occupied by Africans, there were few requests for concessions.

Two factors changed this negative attitude toward the protectorate. The first was the construction of a railway from the coast to Lake Victoria, and the second was the transfer of the western highlands from Uganda to the East Africa Protectorate in 1902. The need for a railway to promote the development of East Africa's economic resources had been emphasized by the Imperial British East Africa Company, and the British prime minister, Lord Salisbury, had favoured the idea, mainly on strategic grounds. There had, however, been strong opposition from anti-imperialists in Britain, and in 1891–92 a preliminary survey only had been carried out by Captain J.R.L. Macdonald. But the declaration of the Uganda protectorate strengthened Lord Salisbury's case, and work began on the construction of the railway at Mombasa in December 1895. The first locomotive reached Kisumu on Lake Victoria in December 1901, and the line was completed in 1903. By this time it had cost the British treasury £5,317,000, and, because of the alteration of the boundary between the two protectorates, it no longer extended to Uganda. To the burden of financing the administration of the East Africa Protectorate was now added the responsibility of making the railway pay. The proceeds of traffic to and from Uganda would still be available to the protectorate administration, but this did not remove the need to develop the resources of the territory to the utmost and as speedily as possibly.

Encouraging European settlement

In these circumstances the decision to encourage extensive European settlement was not surprising. The African peoples were not organized in such a way as to suggest that African agriculture, even under European guidance, would produce the swift returns that the economy of the protectorate demanded. Moreover, the transfer of the highlands from Uganda had placed at the disposal of the administration large tracts of land apparently suited to large-scale farming, virtually uninhabited and situated in a region climatically attractive to Europeans. Even around Nairobi itself, which because of its central position was promoted early in the century from its former status as an important railway stores depot to be the administrative capital of the protectorate, there was apparently a considerable area of fertile, uninhabited land. For many reasons, therefore, the decision of Sir Charles Eliot, who had become commissioner for the protectorate in 1901, to invite European settlers to East Africa appeared sound. Eliot was both a scholar and a humanitarian, so that his policy was not adopted without a full consideration of its likely effects upon the indigenous African population. To make up for the lack of interest of Englishmen in East Africa, Eliot invited South Africans to settle in the protectorate. Since the response was both quicker and greater than had been expected, a hurried survey, based upon inadequate information, was carried out. As a result, small areas of land in Kiambu district, which had formerly been occupied by Africans and which the Kikuyu regarded as part of their legitimate area of expansion, were allocated to white settlers. The area involved was not large, but it served as a justification for all future African criticisms of European settlement.

As the settled area was extended during the first decade of the 20th century into the Rift Valley and on to the highlands beyond, the problem of labour supplies also arose. Much of this land was either uninhabited or supported only a very lightly scattered population. Having been invited to East Africa by the government, the settlers expected that an adequate labour supply would be made available. Because few Africans appeared to be completely occupied all the year round in work on their own farms, to the white settlers there seemed no reason why they should not be invited and, if necessary, compelled to offer their services to European farmers. The Africans, however, accustomed to subsistence farming and requiring only a low standard of material comfort, could see no reason why they should work away from home. Successive commissioners and governors responded in varying degrees to the settlers' demand for the introduction of some form of compulsion to ensure an adequate labour supply, but it was not until immediately after World War I, and largely as a result of a public outcry in Britain, that compulsory labour on either public or private projects was strictly forbidden.

Tribal reserves

Another cause of African discontent was the decision taken soon after Eliot's departure in 1904 to confine the native population to reserves. Although this plan was intended to protect the Africans from excessive competition as well as to leave as much land as possible available for scientific development by European farmers, the fact that the reserves were not gazetted for many years aroused a profound sense of unease among the Africans, for whom land was the only form of social security.

Owing to the Africans' reluctance to work on the construction of the railway, thousands of Indian coolies were brought into the protectorate; but most of these returned to India after their contracts were completed. The opening of the railway had, however, encouraged Indian traders who had formerly lived nearer the coast to penetrate far into the interior, even ahead of the administration, and these men made a valuable contribution to the country's economic development. Other Indians hoped to obtain land, but European settlers strongly resisted any idea of

their encroachment into the highland areas. Conscious of the great efforts they had put into the development of a virgin land and anxious to establish a truly British colony in East Africa, the Europeans consistently opposed the Indians' claim to equality in both political and economic fields.

Before the outbreak of war in 1914, unofficial participation in political affairs was mainly limited to the creation of pressure groups, the most prominent being the Convention of Associations, which had developed in 1911 from earlier European settler organizations. In 1905 an Executive Council had been appointed, and in 1907 the first Legislative Council was convened. Although the latter body consisted at first of only two nominated unofficial members in addition to the six official members, the unofficial members were not slow to uphold the white settlers' cause. The transfer of the control of the protectorate from the Foreign Office to the Colonial Office on April 1, 1905, did not give the settlers the increased responsibility for which they had hoped, and in 1913 they launched a campaign to elect their own representatives to the Legislative Council. The outbreak of World War I put a check upon their hopes, but the prominent part played by elected representatives in the activities of the War Council appointed in September 1915 offered a fair prospect of the early satisfaction of the settlers' claims to elected representation in the country's legislature.

World War I and its aftermath. The threat to the protectorate, and in particular to the vital Uganda Railway, from German East Africa never materialized, and early in 1916 the British advance into German territory finally removed the possibility of further military action on British soil in East Africa. Nevertheless, the war had serious effects upon the protectorate's economy. Most of the white settlers hastened to join the armed forces, leaving their farms to be looked after by their wives or else to revert to wilderness. Thus, at a crucial stage in the agricultural development of the territory, momentum was lost. Immediately after the war an attempt was made to stage a quick revival by the introduction of a "soldier settler" scheme, but the hopes of prosperity encouraged by the postwar demand for primary produce received a severe setback in the early 1920s, when the world depression brought bankruptcy to many of those who had started out with inadequate capital or who had relied upon credit from the banks. The achievement of stability was further delayed by the replacement of the rupee currency, first by a florin currency and shortly afterward, before the florin had been fully accepted, by East African shillings.

Economic depression

The courage, if not the confidence, of the settlers remained unshaken, and by the mid-1920s the country's economy had wholly revived. Although the depression of the early 1930s brought further difficulties to East Africa, the foundations of prosperity had been still further strengthened by a great improvement in rail communications. Already in 1913 railway extensions had been opened to Thika and to the soda deposits at Lake Magadi, and during the war a link was made between the main line and the German railway system to the south.

The most important postwar project was the building of a new extension of the main line across the Uasin Gishu Plateau to tap the agricultural wealth of the highlands, and thence to Uganda in order to provide a ready means of egress for the cotton crops of that protectorate. The line was eventually completed from Nakuru to Jinja in January 1928 and was carried on to Kampala, which it reached in January 1931.

Kenya Colony. *Political movements.* Political considerations then began to usurp the place of prominence formerly occupied by economic problems. In 1920 the status of the East Africa Protectorate was changed to that of Kenya Colony, named after the highest mountain in the country, and the coastal strip leased from the sultan of Zanzibar became the Kenya Protectorate. In the previous year the white settlers had been permitted for the first time to elect members to the Legislative Council, and the Indians began to call for equal treatment. In 1920 they rejected an offer of two elected members on the ground that this would mean that they were not so well represented as the Europeans, and a fierce political struggle broke out between the white settlers and their Indian rivals. In 1923, however, the colonial secretary, the Duke of Devonshire, after hearing representations from both Europeans and Asians, issued a White Paper in which he declared that African interests must be paramount, although minorities would not lose their rights. This pronouncement marked the tentative beginning of an era of "trusteeship" for the African peoples of Kenya. In 1927 the dispute between Europeans and Indians virtually ceased when the Indians accepted 5 seats in the Legislative Council. The Europeans were to have 11 elected representatives.

Trusteeship did not immediately result in any great improvement in the social conditions of the African population. Little provision for education was made by the government, and nearly all the schools for Africans were supplied by missionaries. Africans, too, found no place in the country's legislature, their interests being represented by the official members of the council and by a European unofficial member, usually a missionary. With the example of the Convention of Associations before them, however, the Africans developed their own pressure groups. Among the Kikuyu, who supplied a considerable proportion of the labour force on the European farms and whose proximity to Nairobi brought many of them into regular contact with Europeans, organizations to represent the tribe's grievances began to spring up quickly in the 1920s and 1930s. The most prominent was the Young Kikuyu Association, founded in 1921, which in 1925 was renamed the Kikuyu Central Association. In demanding African representation in the legislature, the association was in advance not only of the government but also of most of the members of the tribe. It won support among the Kikuyu, however, when it complained about low wages, the prohibition of coffee growing by Africans, and the condemnation by Christian missionaries of such tribal practices as clitoridectomy. The association never represented the tribe as a whole, though, because its members were mainly young men whom the chiefs did not trust. For this reason, too, the European administration tended to look with disfavour upon its activities. Attempts to win the support of other tribes failed owing to their unwillingness to accept Kikuyu leadership.

African political groups

Another cause for political concern was the proposal, first made toward the end of World War I, to introduce some form of closer union between Uganda, Kenya, and the former German possessions in East Africa. A number of commissions visited East Africa between 1924 and 1929 to investigate means of implementing the plan, but in the face of local opposition the idea was dropped early in the 1930s. At the outset the white settlers of Kenya opposed closer union with the other territories through fear of African domination. In view of the apparent determination of the British government, however, they agreed in the later 1920s to a compromise that would protect their political status in Kenya. In the 1930s they went further and actively supported union with Tanganyika as a protection against Germany's claims to its former overseas dependencies.

World War II to independence. The outbreak of World War II again checked development, and the entry of Italy into the war for a time threatened the security of Kenya's northern border with Ethiopia and Somaliland. The Italians were soon defeated, however, and troops from Kenya then took part in campaigns in many parts of the world. In Kenya itself the main objective was to achieve the highest possible degree of economic self-sufficiency. Political progress was not neglected, and in 1944 Kenya became the first East African territory to include an African in its Legislative Council. The number was increased to two in 1946, four in 1948, and eight in 1951. All were appointed by the governor from a list of names submitted to him by local governments. In 1948 the East Africa High Commission was set up to administer certain services of common benefit to Kenya, Uganda, and Tanganyika. With headquarters in Nairobi, it consisted of the governors of the three territories, with the governor of Kenya serving as chairman.

Both political progress and the large-scale economic de-

The Mau Mau Rebellion

velopment program initiated soon after the war received a severe setback in the 1950s with the outbreak of the Mau Mau Rebellion, which necessitated the proclamation of a state of emergency in October 1952. The rising was limited to the Kikuyu tribe and was directed against the presence of Europeans in Kenya and their ownership of land. Nonetheless, during the years of violence that followed, it was those Kikuyu who failed to support the Mau Mau secret society who suffered most heavily. Jomo Kenyatta, charged with directing the Mau Mau movement and sentenced with five associates to seven years' imprisonment in 1953, was released in 1959 and confined to restrictive residence. A considerable military campaign was needed to destroy the rebellion, and years of rehabilitation were required before order was restored. The emergency was brought to an end early in 1960.

Numerous economic and social changes resulted either directly or indirectly from the Mau Mau rising. One of the most important was the centralization of the Kikuyu in large villages, which was accompanied by a land consolidation program. This plan was also extended to Nyanza region near Lake Victoria. Considerable sums of money were set aside to encourage higher standards of African cultivation, and coffee became one of the principal crops. Throughout the years of uncertainty, foreign investment in Kenya continued. Limited industrial development took place with agricultural expansion.

In spite of the upheaval, successive colonial secretaries persisted in their attempt to promote political progress among the African population. In March 1957 elections were held on a qualitative franchise for the eight African seats in the legislature. In 1958 there were further proposals for an increase in African membership of the council, and a council of state was set up to scrutinize legislation that might involve discriminatory measures against certain sections of the people. The former rivalry between Europeans and Indians was now giving way to a rivalry between Europeans and Africans, and further constitutional advancement pointed the way to majority rule by Africans in Kenya. As a result of a conference held in London in 1960, Africans became the majority in the Legislative Council and obtained 4 of the 10 unofficial portfolios in the Council of Ministers.

To meet this challenge, two African political parties were formed: the Kenya African National Union (KANU), led by Tom Mboya and later by Jomo Kenyatta; and the Kenya African Democratic Union (KADU), led by Ronald Ngala. The former drew most of its support from the Kikuyu and Luo tribes and favoured a strong, centralized government; the latter originated among the smaller tribes who sought to avoid Kikuyu domination by advocating a federal form of government. A coalition government of the two parties was formed in 1962, but after elections in May 1963 KANU took office, with Kenyatta as prime minister, under a new constitution that gave Kenya self-government. Following further discussions in London, Kenya became fully independent in December 1963, and Zanzibar surrendered its sovereignty over the Kenya Protectorate to Kenya. A year later Kenya became a republic, with Kenyatta as its first president and Oginga Odinga as vice president.

Formal independence

The Republic of Kenya. *Kenyatta's rule.* In 1964 an army mutiny was suppressed when Kenyatta sought the help of British troops. The president then acted decisively: better conditions of service were introduced, promotion prospects were improved, and the proportion of Kenyatta's own Kikuyu people in the officer corps was steadily increased. At the same time, most KADU members transferred their allegiance to KANU, and KADU ceased to exist. To forestall any new opposition, Kenyatta tried consistently to appoint members of different ethnic groups to official posts with all the patronage the appointments conferred, but he relied most heavily on Kikuyu, whom he believed he could trust. Ideological differences led to disagreement with Vice President Odinga, whose appointment had been made to satisfy the powerful Luo. Odinga believed that, by adopting a pro-Western, essentially capitalist economic policy, the government was neglecting the interests of poorer people. Breaking with KANU to form a new opposition party, the Kenya People's Union (KPU), Odinga found his position weakened by legislation requiring elected officials who switched parties to resign their seats and run for reelection. By contrast, Kenyatta's authority was strengthened because of the greater powers now attributed to the office of president.

The distribution to Africans of hundreds of thousands of smallholdings, made available by a satisfactory financial settlement with European farmers who were prepared to leave the country amicably, enabled Kenyatta to challenge Odinga's assertion that the poor were not catered to. The inability of some smallholders to offer the flexibility needed to meet the changing market demand for their produce meant that not all the new landowners were successful. There was, nevertheless, a sufficiently widespread improvement in living standards to ensure continuing support for the government.

The assassination in July 1969 of Mboya, who had become minister of economic planning and development, widened still further the serious ethnic gap that had already emerged as a result of Odinga's fall from grace. Mboya, like Odinga, was a Luo, though neither had pursued ethnic goals. Their supporters among the Luo, however, believed there was a Kikuyu plot, centring upon Kenyatta, which threatened Luo interests. The division grew greater after October 1969, when Odinga and some of his leading party members were arrested and the KPU was banned. The arrested men were subsequently released, and Odinga himself was freed in 1971 when the president endeavoured to achieve a measure of reconciliation and national unity. His efforts were not wholly successful, however, and the transfer of more than 1.5 million acres of land to a group of wealthy Kenyans, many of them Kikuyu, though defensible on grounds of potential economic efficiency, did not prove as profitable as had been hoped, largely because of bad management. Inevitably, the move provided fuel for those who, like Odinga, accused the government of being uncaring and for those who believed there was an ethnic plot to benefit the Kikuyu.

Suspicion of Kikuyu influence

A further suspected army coup attempt was forestalled in 1971. Once again Kenyatta responded by improving pay and conditions of service, but at the same time he made sure that the army remained small in numbers. Odinga and other former KPU leaders were prevented from standing in the parliamentary elections of 1974 by new regulations that forbade the candidacy of anyone who had not been a member of KANU for the past three years. The challenge to Kenyatta was then taken up in parliament by another former supporter of KANU, J.M. Kariuki. Kariuki was critical of growing corruption in the government, and he won considerable support when increasing oil prices and the consequent worldwide inflation caused hardship among the poorer members of the community. His arrest and murder in March 1975, which the government tried to cover up, aroused angry protests, particularly among university students whose criticisms of the government were to have increasing significance.

The question of who should succeed the aging president exacerbated the disagreements already prominent among the country's leaders. Kenyatta himself encouraged no one to claim the inheritance, but leading Kikuyu who had benefited greatly under his leadership plotted to secure a complaisant successor. The attorney general, Charles Njonjo, though himself a Kikuyu, opposed this move, as did another Kikuyu, the minister of finance, Mwai Kibaki. Together the two ensured that, upon Kenyatta's death in August 1978, he was succeeded by his deputy, Daniel arap Moi, a member of the minority Kalenjin group of peoples. Moi was elected president in October; Kibaki became vice president.

Moi's rule. Misgivings about what would happen on the departure of the dominating figure who had led his country to independence were soon dispelled. The transfer of power took place smoothly, owing mainly to the skillful leadership of Njonjo and Kibaki but also helped by a recent boom in coffee prices, which had eased the country's economic problems to a considerable extent. At first Moi followed Kenyatta's example by distributing offices among as wide an ethnic spectrum as possible, though over the

years members of his own Kalenjin group acquired a disproportionate number of appointments. Odinga remained critical of the government, and university students rallied to his support on idealistic grounds and also because they saw little prospect in the near future of being able to occupy the limited number of lucrative offices now held by their immediate predecessors.

Stifling opposition to the president

It was, however, Njonjo whom Moi saw as the main threat to his position. Exercising his almost unassailable presidential powers, he began a campaign of denigration against the former kingmaker. Njonjo's responsibilities were cut, as, too, were those of Kibaki. The strength of Moi's position was further underlined when the army loyally rallied to suppress an attempted coup by some of the lower ranks of the air force in 1982. Significantly, a number of the leaders of the rebellion were Luo, and many university students also took part in the disturbances. Anxious to prevent the students from becoming effective leaders of discontented groups of ethnic or impoverished minorities, the president resorted to closing the universities temporarily if opposition was voiced.

Generous financial support from the Western powers since independence had been an important factor in ensuring that Kenya's precarious economy survived the traumas of inflation. Kenyatta had set the pattern of aligning his country with the West, and Moi was happy to follow suit. The extension of land ownership among Africans in the postindependence period also helped to create a prosperous class that was anxious to avoid revolutionary change, while the powers vested in the office of president made successful opposition an unlikely prospect. (K.In.)

Increasingly, however, Western financial aid came to be tied to demands for political and economic reforms, and Moi finally accepted a 1991 constitutional amendment that reinstated multiparty elections. In elections held the following December, however, Moi was reelected, and the opposition was divided.

Moi made Njonjo chairman of the Kenya Wildlife Services and Richard Leakey head of the civil service and permanent secretary to the cabinet in 1999 (Leakey left in 2001). Leakey's popularity was cited as the main reason Moi appointed him to this post; it was also seen as Moi's way of showing Kenya's commitment to tackling the issues of corruption and government mismanagement, issues that continued to plague the country as did concerns over who would succeed Moi when he retired. Another major concern was the growing number of AIDS cases. (Ed.)

For later developments in the history of Kenya, see the BRITANNICA BOOK OF THE YEAR.

Tanzania

The United Republic of Tanzania (in Swahili, Jamhuri ya Muungano wa Tanzania) is situated just south of the Equator, bordered by the Indian Ocean on the east and eight other nations: Kenya, Uganda, Rwanda, Burundi, Congo (Kinshasa), Zambia, Malaŵi, and Mozambique. Tanzania was formed as a sovereign state in 1964 through the union of the theretofore separate states of Tanganyika and Zanzibar. The combined territories comprise 364,017 square miles (942,799 square kilometres), with mainland Tanganyika covering more than 99 percent of the total area. Mafia Island is administered from the mainland, while Zanzibar and Pemba islands have a separate government administration. Dodoma, since 1974 the official capital of Tanzania, is centrally located on the mainland. Dar es Salaam, however, remains the seat of most government administration and is the country's largest city.

PHYSICAL AND HUMAN GEOGRAPHY

The land: Tanzania mainland. *Relief.* Except for the narrow coastal belt of the mainland and the offshore islands, most of Tanzania lies above 600 feet (200 metres) in elevation. Vast stretches of plains and plateaus contrast with spectacular relief features, notably Africa's highest mountain, Kilimanjaro (19,340 feet [5,895 metres]), and the world's second deepest lake, Lake Tanganyika (4,710 feet [1,436 metres] deep).

The East African Rift System runs in two north–south-trending branches through Tanzania, leaving many narrow, deep depressions that are often filled by lakes. One branch, the Western Rift Valley, runs along the western frontier and is marked by Lakes Tanganyika and Rukwa, while the other branch, the Eastern (or Great) Rift Valley, extends through central Tanzania from the Kenyan border in the region of Lakes Eyasi, Manyara, and Natron south to Lake Nyasa at the border with Mozambique. The Central Plateau, covering more than a third of the country, lies between the two branches.

The Rift Valley

Highlands associated with the Western Rift Valley are formed by the Ufipa Plateau, the Mbeya Range, and Rungwe Mountain in the southwestern corner of the country. From there the Southern Highlands run northeastward along the Great Rift to the Ukuguru and Nguru mountains northwest of Morogoro. Extending from the northern coast, the Usambara and Pare mountain chains run in a southeast-to-northwest direction, culminating in Kilimanjaro's lofty, snow-clad peak and continuing beyond to Mount Meru (14,980 feet). Immediately to the west of Mount Meru, another chain of mountains begins, which includes the still-active volcano Ol Doinyo Lengai and the Ngorongoro Crater, the world's largest caldera, or volcanic depression. This chain extends through a corridor between Lake Eyasi and Lake Manyara toward Dodoma.

Drainage. Because of its numerous lakes, approximately 22,800 square miles of Tanzania's territory consists of inland water. Lake Victoria, which ranks as the world's second largest freshwater lake, is not part of the Rift System. Interestingly, Tanzania has no big rivers, yet it forms the divide from which the three great rivers of the African continent rise—the Nile, Congo, and Zambezi, which flow to the Mediterranean Sea, the Atlantic Ocean, and the Indian Ocean, respectively. Separated by the Central Plateau, the watersheds of these rivers do not meet.

Ol Doinyo Lengai, volcano near Lake Natron, northern Tanzania
Robert Francis/Robert Harding Picture Library

All of Tanzania's major rivers—the Ruvuma, the Rufiji, the Wami, and the Pangani—drain into the Indian Ocean. The largest, the Rufiji River, has a drainage system that extends over most of southern Tanzania. The Kagera flows into Lake Victoria, whereas other minor rivers flow into internal basins formed by the Great Rift Valley. With so many rivers, Tanzania is rich in hydroelectric potential.

Soils. The variety of soils in Tanzania surpasses that of any other country in Africa. The reddish brown soils of volcanic origin in the highland areas are the most fertile. Many river basins also have fertile soils, but they are subject to flooding and require drainage control. The red and yellow tropical loams of the interior plateaus, on the

other hand, are of moderate-to-poor fertility. In these regions, high temperatures and low rainfall encourage rapid rates of oxidation, which result in a low humus content in the soil and, consequently, a clayey texture rather than the desired crumblike structure of temperate soils. Also, tropical downpours, often short in duration but very intense, compact the soil; this causes drainage problems and leaches the soil of nutrients.

Climate. Tanzania is subject to a warm, equatorial climate modified by variations in elevation. The high amount of solar radiation throughout the year is associated with a limited seasonal fluctuation of temperature: the mean monthly variation is less than 9° F (5° C) at most stations. Ground frosts rarely occur below 8,200 feet.

Rainfall and agriculture

Rainfall is highly seasonal, being influenced greatly by the annual migration of the intertropical convergence zone. Roughly half of Tanzania receives less than 30 inches (750 millimetres) of rainfall annually, an amount considered to be the minimum required for most forms of crop cultivation in the tropics. The Central Plateau, the driest area, with less than 20 inches per year on average, experiences a single rainy season between December and May. Rainfall is heavier on the coast, where there are two peaks of rainfall in October–November and April–May. The offshore islands and many highland areas have high annual rainfall totals of over 60 inches.

Plant and animal life. Forests grow in the highland areas where there is high rainfall and no marked dry season. The western and southern plateaus are primarily miombo woodland, consisting of an open cover of trees, notably *Brachystegia, Isoberlinia, Acacia,* and *Combretum.* In areas of less rainfall (16–32 inches), bushland and thicket are found. In the floodplain areas, wooded grassland with a canopy cover of less than 50 percent has been created by poor drainage and by the practice of burning for agriculture and animal grazing. Similarly, grassland appears where there is a lack of good drainage. For example, the famous Serengeti Plain owes its grasslands to a calcrete, or calcium-rich hardpan, deposited close to the surface by evaporated rainwater. Swamps are found in areas of perennial flooding. Desert and semidesert conditions range from an Alpine type at high altitudes to saline deserts in poorly drained areas and arid deserts in areas of extremely low rainfall.

Due to the historically low density of human settlement, Tanzania is home to an exceptionally rich array of wildlife. Large herds of hoofed animals—most spectacularly the wildebeest, as well as the zebra, giraffe, buffalo, gazelle, eland, dik-dik, and kudu—are found in most of the country's numerous game parks. Predators include hyenas, wild dogs, and the big cats—lions, leopards, and cheetahs. Crocodiles and hippopotamuses are common on riverbanks and lakeshores. The government has taken special measures to protect the rhinoceros and elephant, which have fallen victim to poachers. Small bands of chimpanzees inhabit Gombe National Park along Lake Tanganyika. Nearly 1,500 varieties of birds have been reported, and there are numerous species of snakes and lizards.

Settlement patterns. The two most important factors influencing the regional pattern of human settlement are rainfall and the incidence of tsetse fly. The tsetse, which thrives on wild game in miombo woodlands, is the carrier of *Trypanosoma,* a blood parasite that causes sleeping sickness in cattle and people. Tsetse infestation makes human settlement hazardous in areas of moderate rainfall, so that areas of low and unreliable rainfall are more densely populated than would otherwise be the case. The insect does not pose a threat to areas of high rainfall and high population density.

Centres of population

Population is concentrated in the highlands of the Mbeya Range, Kilimanjaro, and the Bukoba area west of Lake Victoria, on the cultivation steppe south of Lake Victoria, in the moderately high-rainfall region of Mtwara on the southern coast, and in the urban area of Dar es Salaam. These areas are all located on the perimeter of the country. The influence of the central rail line is clearly evident in the corridor of moderate population density extending from Dar es Salaam to Lake Victoria. Three sparsely populated areas stand out: the arid area of Arusha in the north and the two large tsetse-infested areas centred around Tabora in the west and Lindi and Songea in the south.

Regional variations in agricultural productivity are strongly related to the pressure of population on the land. Shifting cultivation, which involves rotating crops annually and leaving some fields to lie fallow for 20 years or more, was traditionally the means of renewing the fertility of the soil throughout Tanzania (with the exception of the more fertile and densely populated highland areas). A settlement pattern of widely dispersed, isolated farmsteads resulted from this practice. As the rural population expanded, however, fallow periods became shorter, and consequently soil fertility and crop yields suffered. In order to raise productivity, during the 1960s and '70s the government tried to bring about the use of improved agricultural methods, equipment, and fertilizer through the nucleation of rural settlements. First, the *ujamaa* (or "familyhood") policy of the 1960s supported collectivized agriculture in a number of government-sponsored planned settlements. These settlements were over-reliant on government finance and gradually dwindled in number. On a much larger scale, the "villagization" program of the 1970s moved millions of peasants into nucleated villages of 250 households or more. By 1978 there were more than 7,500 villages, in comparison to only about 800 in 1969. Villagization was aimed not at collectivizing agriculture but at facilitating the distribution of agricultural inputs such as fertilizers and improved seeds as well as making social services more accessible to the rural population.

Only about 15 percent of the population lives in urban areas, and one-third of the urban population resides in Dar es Salaam, a city of more than one million people. Bagamoyo and Tabora, old towns connected with the 19th-century Arab slave trade, have stagnated. The fortunes of Tanga, the second largest city during the British colonial period, have been tied to the export of sisal; as that has declined, the city has grown very slowly, although it remains the country's third largest city. Mwanza, Mbeya, and Arusha have thrived as trading centres remote from Dar es Salaam, and the growth of Morogoro and Moshi reflects their rich agricultural hinterlands. (D.F.Br.)

Important trading towns

The land: Zanzibar and Pemba. *Relief.* Low-lying Pemba, whose highest point reaches an elevation of 311 feet, and Zanzibar, which reaches 390 feet, are islands whose structure consists of coralline rocks. The west and northwest of Zanzibar consist of several ridges rising above 200 feet, but nearly two-thirds of the south and east are lowlying. Pemba appears hilly because the level central ridge has been gullied and eroded by streams draining into numerous creeks. On Zanzibar Island short streams drain mostly to the north and west. The few streams in the east disappear into the porous coralline rock.

Soils. Among the 10 types of soils recognized in Zanzibar are fertile sandy loams and deep red earths, which occur on high ground; on valley bottoms, less fertile gray and yellow sandy soils are found. The eight soil types in Pemba include brown loams; pockets of infertile sands are found on the plains.

Climate. Zanzibar and Pemba have rainfall of 60 inches and 80 inches, respectively. The rainfall is highest in April and May, lowest in November and December. Humidity is high. The average temperature is 81° F (27° C) in Zanzibar and 79° F (26° C) in Pemba; the annual temperature ranges are small.

Vegetation. Long human occupation has resulted in the clearance of most of the forests, which have been replaced with coconuts, cloves, bananas, citrus, and other crops. On the eastern side of the islands, especially on Zanzibar, there is bush (scrub).

Animal life. Although there is some difference between the animal life of the two islands, it is generally similar to that on the mainland. Animal life common to both islands includes monkeys, civet cats, and mongooses. More than 100 species of birds have been recorded in Zanzibar.

Rural settlements. The rural settlements—and the life in them—changed drastically after the nationalization of land in 1964 and subsequent agricultural reforms. By 1970, large plantations of cloves and coconuts, once al-

most exclusively the property of fewer than 50 Arab families, had been redistributed. The production of food crops, especially rice, is being encouraged. Fishing villages are still important in the east.

Urban settlements. The city of Zanzibar is still primarily a Muslim town, although the distinctive mode of life and culture, reminiscent of an Eastern commercial centre, has almost disappeared since the downfall of the Arab oligarchy in 1964. The hub of civic life is moving from Stone Town with its narrow lanes to a new town with modern buildings and amenities at Ngambo, the former African quarter. Kilimani, Bambi, and Chaani are being developed into new rural towns; a similar change is taking place in Pemba at Mkoani, Chake Chake, and Wete. (A.C.M.)

Ethnic variety

The people: Tanzania mainland. *Ethnic composition.* Tanzania is extremely heterogeneous, with more than 120 different indigenous African peoples as well as small groups of Asians and Europeans. As early as 5000 BC, San-type hunting bands inhabited the country. The Sandawe hunters of northern Tanzania are thought to be their descendants. By 1000 BC, agriculture and pastoral practices were being introduced through the migration of Cushitic people from Ethiopia. The Iraqw, Mbugu, Gorowa, and Burungi have Cushitic origins. About AD 500, iron-using Bantu agriculturalists coming from the west and south started displacing or absorbing the San hunters and gatherers; at roughly the same time, Nilotic pastoralists entered the area from the southern Sudan. Today the majority of Tanzanians are of Bantu descent; the Sukuma constitute the largest group, and others are the Nyamwezi, Hehe, Nyakyusa, Makonde, Yao, Haya, Chaga, Gogo, and Ha. Nilotic peoples are represented by the Masai, Arusha, Samburu, and Baraguyu. No one group has been politically or culturally dominant, although the tribes that were subject to Christian missionary influence and Western education during the colonial period (notably the Chaga and Haya) are now disproportionately represented in the government administration and cash economy.

There are also Asian and European minorities. During the colonial period, Asian immigration was encouraged, and Asians dominated the up-country produce trade. Coming mostly from Gujurāt in India, they form several groups distinguished by religious belief: the Ismāʿīlīs, Bohrās, Sikhs, Punjabis, and Goans. Since independence the Asian population has steadily declined due to emigration. The European population, never large because Tanganyika was not a settler colony, was made up primarily of English, Germans, and Greeks. In the postindependence period, a proliferation of different European, North American, and Japanese expatriates connected with foreign aid projects have made Tanzania their temporary residence.

Language. Swahili is the national language. Virtually all Tanzanians speak the language, and it is used as the medium of instruction in the first seven years of primary education. English, the country's second official language (together with Swahili), is the medium of instruction at further levels of education and is commonly used by the government in official business. Most African Tanzanians speak their traditional tribal language as well. The main languages spoken by the Asian minorities are Gujarati, Hindi, Punjabi, and Urdu.

Religion. Roughly one-third of the population is Muslim, another third professes Christianity, and the remainder is considered to hold animist beliefs. The division is usually not as clear as official statistics suggest, since many rural Tanzanians adhere to elements of their traditional animistic religions while practicing their Islāmic or Christian faith. A wide array of Christianity is represented, notably Lutheranism and Roman Catholicism. Among Muslims, both the Sunnite and Shīʿite sects are represented. The majority of Asian Muslims are Ismāʿīlī Khōjās under the Aga Khan's spiritual leadership. In addition, there are Asian adherents to Hinduism, Jainism, and Roman Catholicism.

The growing population

Demographic trends. Tanzania's population growth rate is one of the highest in sub-Saharan Africa. Despite great improvements since the 1950s, the infant and child mortality rates remain high, but fertility is high as well. Nearly 50 percent of Tanzanians are under the age of 15. Life expectancy, at about 53 years, is above average for the subcontinent. (D.F.Br.)

The people: Zanzibar and Pemba. *Language.* Swahili is the principal language in Zanzibar and Pemba. The classical dialect is Kiunguja. Arabic is also important because of long-established Islāmic tradition, past Arab overlordship, and the presence of a large Arab-speaking minority. Among the Asian communities, the chief languages are Gujarati, Kutchi, and Hindustani. English, taught in schools, is widely used.

Ethnic groups. There are several groups of Africans, nearly one-third of whom are recent arrivals from the mainland. Indigenous Bantu groups, consisting of the Pemba in Pemba and the Hadimu and Tumbatu in Zanzibar, have absorbed the settlers who came from Persia in the 10th century. These groups and some of the descendants of slaves call themselves Shirazi. There are also small enclaves of Comorians and Somalis. Arab settlements were also established early, and intermarriage with the local people took place. Later Arab arrivals came from Oman and constituted an elite. The poorer recent immigrants from Oman are known as Manga. The Asians, now forming a very small minority, may be divided into Muslim and non-Muslim groups.

Religion. Almost the whole of the Arab and the African peoples of Zanzibar profess the Islāmic faith. Traditional African beliefs are also found existing in conjunction with Islām. Among Muslims, the Sunnite sect is preferred by the indigenous people. (A.C.M.)

The economy. The Tanzanian economy is overwhelmingly agrarian in nature and reflects the leadership's political commitment to socialist development and central planning. Agriculture constitutes over half of the gross domestic product (GDP) and some 80 percent of export earnings, and it provides a livelihood for about nine-tenths of the economically active population. Industry accounts for less than 10 percent of the GDP, and mining less than 1 percent, whereas services, including public administration, produce approximately one-third of the GDP. A number of industries and public services were nationalized at the time of the Arusha Declaration in 1967, when the intention to build a socialist state was announced.

Economic troubles

Beginning in 1979 and continuing throughout the 1980s, the international oil price rise, the country's declining terms of trade, and the sluggishness of the domestic economy brought about rapid inflation, the emergence of an unofficial market (consisting of the smuggling of goods abroad in order to avoid taxes and price controls), and a government fiscal crisis. Despite attempts to cut imports to the barest minimum, the trade deficit widened to an unprecedented level, and the balance-of-payments problem became so acute that development projects had to be suspended. This economic crisis forced the government to secure a loan from the International Monetary Fund (IMF) in 1986. The loan's conditions required the elimination of subsidies and price controls as well as some social services and staff positions in state-run enterprises. Thereafter, the government continued to implement measures intended to create a mixed economy and reduce the extent of the untaxable unofficial markets.

Agriculture. The major food crops are corn, rice, sorghum, millet, bananas, cassava, sweet potatoes, barley, potatoes, and wheat. Corn and rice are the preferred cereals, whereas cassava and sweet potatoes are used as famine-prevention crops owing to their drought-resistant qualities. In some areas food crops are sold as cash crops. Peasants in the Ruvuma and Rukwa regions, for example, have specialized in commercial corn production, and in riverine areas, especially along the Rufiji, rice is sold.

Export cash crops provide the major source of foreign exchange for the country. Coffee and cotton are by far the most important in this respect, but exports of tea, cashew nuts, tobacco, and sisal are also substantial. Cloves are Zanzibar's main export. Once the source of over 90 percent of the world's cloves, Zanzibar now produces only about 10 percent of the international supply.

The villagization program of the mid-1970s was followed by government efforts to distribute improved seed corn and fertilizers through the new village administrations, but

timely distribution of such agricultural inputs was largely thwarted by the logistical problems of transporting them to the villages. Nevertheless, increased yields, attributed to the use of chemical fertilizers, have been achieved in peasant corn production in the south and southwestern regions.

Industry. Tanzania's industry is based on the processing of its agricultural goods and on import substitution—that is, the manufacture (often from imported materials and parts) of products that were once purchased from abroad. The principal industries are food processing, textiles, brewing, and cigarettes. Production of clothing, footwear, tires, batteries, and bottles takes place as well. There is also a hot-rolling steel mill, a factory producing asbestos cement sheets, a bicycle factory, and a large pulp and paper mill.

A strategy to lay the foundation for the rapid growth of such basic industries as steel, chemicals, rubber, and textiles was thwarted by the national economic crisis of the 1980s. The large amounts of imported materials, parts, and capital equipment necessary to implement such a policy could not be paid for, owing to the country's lack of foreign exchange. Standby credit facilities from the IMF provided the capital investment needed to initiate a rehabilitation of industry.

Mineral deposits

Resources. Tanzania mines diamonds, gold, kaolin, gypsum, tin, and various gemstones, including tanzanite. There are large exploitable deposits of coal in the southwest, phosphate deposits in Arusha, and nickel in the Kagera region. Natural gas has been discovered at Songo Songo Island. Several international companies have been involved in onshore and offshore petroleum exploration.

Tanzania's native forests are primarily composed of hardwoods, but softwood production is increasing. A large pulp and paper mill at Mufindi is supplied by the extensive softwood forest nearby at Sao Hill. Because firewood and charcoal are the major domestic fuels, there is growing concern about the deforestation of land in the hinterland of Dar es Salaam and Tanzania's other large towns.

Several lakes, especially Lake Victoria, are important sources of fish. Prawns are commercially fished in the Rufiji River delta, but coastal fishery is primarily of an artisanal nature.

Finance and trade. All private banks were nationalized between 1967 and 1992, but since then private banks (including branches of foreign-owned banks) have been allowed to open. The state-run Bank of Tanzania operates as the central bank; it manages the country's finances and issues the currency, the Tanzanian shilling.

Transportation. Transport in Tanzania spans a wide spectrum, from the motorized means made possible by roads, railways, seaports, and airfields to the traditional carrying of loads by animals and people. It is estimated that the average peasant household carries by headload approximately 56 ton-miles (90 ton-kilometres) of firewood, water, and crops per year.

Roads are by far the most important nontraditional mode of transport, carrying some 70 percent of total traffic. The

The road network

road network extends to all parts of the country, but it is densest along the coast and southeast of Lake Victoria. The country's percentage of roads paved is one of the lowest in sub-Saharan Africa. The Tanzam Highway, opened in the early 1970s between Dar es Salaam and Zambia, has significantly reduced the isolation of southern Tanzania. A newer highway intersects it at Makambako and proceeds southward through the southern highlands to Songea. Government efforts have been placed on rehabilitating the trunk road system, which deteriorated with a decline in the importation of maintenance materials during the economic crisis.

Dar es Salaam port, with its deep-water berths, handles about three-fourths of all ships calling at Tanzanian ports. The remainder go primarily to Tanga, Mtwara, and the port of the city of Zanzibar. The Tanzania Coastal Shipping Line offers transport services along the coast; a passenger ferry operates between Dar es Salaam and Zanzibar.

The Air Tanzania Corporation provides internal air services as well as international flights to destinations in central and southern Africa, the Persian Gulf, and the Indian Ocean. There are international airports at Dar es Salaam, Kilimanjaro, and Zanzibar, but most scheduled international flights land in Dar es Salaam.

The railway system dates back to the pre-World War I, German-built Central Railway Line, which bisects the country between Dar es Salaam and Kigoma, and the Tanga-to-Moshi railway. Today there is also a branch between these two lines, and another line connects Mwanza with Tabora on the Central Line. The TAZARA rail line, running between Dar es Salaam and Kapiri-Mposhi on the Zambian border, was built with Chinese aid in the early 1970s.

Administration and social conditions. *The government.* The Interim Constitution of 1965 established the United Republic of Tanzania through the merger of Tanganyika and Zanzibar, until then separate and independent countries. A permanent constitution for the United Republic was approved in 1977 and amended in 1984 to include a bill of rights.

Zanzibar has a separate constitution, approved in 1979 and amended in 1985. The executive branch is composed of an elected president and a cabinet called the Supreme Revolutionary Council. Zanzibar's parliament, the House of Representatives, is made up of elected and appointed members. These political bodies deal with matters internal to Zanzibar. Since the union with Tanganyika, some segments of Zanzibari society have occasionally demanded greater autonomy from the mainland. (D.F.Br.)

The president of the United Republic is the head of state and commander in chief of the armed forces. The cabinet of ministers is advisory to the president. Prior to 1995 it included two vice presidents: the prime minister, who is appointed by the president and acts as the leader of the cabinet, and the president of Zanzibar. Since then an amendment to the constitution, which was approved in 1994 and took effect after the 1995 general election, rescinded the stipulation that called for the president of Zanzibar to serve as a vice president.

According to the 1984 constitutional amendments, most members (216 in the 1990 election) of the National Assembly are directly elected. Many seats also are allocated to ex-officio, nominated, and indirectly elected members—including those seats reserved for women, representatives of mass organizations, and the president's nominees. The National Assembly has a term of five years but can be dissolved by the president before this term expires.

The National Assembly

By law Tanzania was a one-party state until 1992, when the constitution was amended to establish a multiparty political process. In 1977 the Tanganyika African Nationalist Union, which had led the colony to independence, and the Afro-Shirazi Party of Zanzibar, which had taken power after a coup in 1964, were amalgamated into the Revolutionary Party (Chama cha Mapinduzi; CCM). Prior to the 1992 amendment, the CCM dominated all aspects of political life, and there was no clear separation of party and government personnel at regional and district levels. By the time of the first national multiparty election in 1995, more than a dozen opposition political movements were officially registered.

For administrative purposes, mainland Tanzania is divided into 20 regions. Each region is administered by a commissioner who is appointed by the central government. At district, division, and ward levels, there are popularly elected councils with appointed executive officers.

(D.F.Br./Ed.)

The judiciary. Tanzania's judiciary is appointed by the president in consultation with the chief justice. Judges cannot be dismissed except on the grounds of misbehaviour or incapacity. A network of primary and district courts has been established throughout the country. English, Islāmic, and customary laws have been absorbed into the legal system. In Zanzibar the highest judicial authority is the Supreme Council. Muslim courts deal with marriage, divorce, and inheritance.

Education. The government-supported education system has three levels: primary (seven years), secondary (four to six years), and university, as well as vocational training schools. During the mid-1970s universal primary education was made mandatory, resulting in a vast increase in primary-school children. Popular pressure for

the expansion of secondary schools has outstripped the availability of government finance. As a result, private secondary schools sponsored by religious institutions and, most notably, by parents themselves have expanded in number. There are two universities, the University of Dar es Salaam (1961), formerly part of the University of East Africa, and Sokoine University of Agriculture (1984). Extensive adult education has focused on eradicating illiteracy, and, as a result, Tanzania has one of the highest literacy rates in Africa.

Health and welfare. National and local governments support a network of village dispensaries and rural health centres; hospitals are located in the urban areas. Private doctors and religious organizations provide medical facilities as well.

Preventing disease

The emphasis of national health policy has been on preventive medicine, especially better nutrition, maternal and child health, environmental sanitation, and the prevention and control of communicable diseases. The main communicable diseases are poliomyelitis, leprosy, tuberculosis, dysentery, enteric fevers, and AIDS. Environmental diseases include malaria, sleeping sickness, bilharzia, and onchocerciasis (river blindness). Inadequate nutrition, particularly of children, is a major concern. Improvements in health and reduction of mortality rates have resulted from the provision of medical care to the rural population and from an inoculation program for children.

Cultural life. Olduvai Gorge, in the Great Rift Valley, is the site of the discovery of some of the earliest known remains of human ancestry, dating back 1,750,000 years. The ancient in-migration of Cushitic, Nilotic, and Bantu peoples, displacing the native San-type population, resulted in a complex agglomeration of tribal communities practicing complementary forms of pastoral and agricultural livelihoods. In the last 500 years, Portuguese, Arab, Indian, German, and British traders and colonists have added to the mosaic. Today Tanzania's multiethnic and multiracial population practices a variety of traditions and customs that form a rich cultural heritage.

The role of kin is central to Tanzanian social and recreational life. Visiting kin on joyous and sorrowful family occasions is given high priority despite the inconvenience caused by a relatively undeveloped transport system. Educated members of the extended family are frequently held responsible for the education and welfare of younger siblings.

Association football (soccer) is a popular sport. In international competitions, Tanzanian sportsmen have excelled in long-distance running.

Oral storytelling traditions and tribal dancing are an important part of the cultural life of the rural population. The University of Dar es Salaam has an active theatre arts group. Among the visual arts, Makonde carvers from southern Tanzania are renowned for their abstract ebony carvings, and Zanzibar is famous for its elaborately carved doors and Arab chests. Basket weaving, pottery, and musical instrument making are prevalent in many rural areas.

Tanzania has government-owned Swahili and English daily newspapers. The radio, more than newspapers or television, is the medium through which the rural population receives national and international news. The radio has been extensively used by the government for the promotion of adult literacy, better nutrition, and ecological conservation. (D.F.Br.)

HISTORY

Tanganyika. *Early exploration.* Most of the known history of Tanganyika before the 19th century concerns the coastal area, although the interior has a number of important prehistoric sites, including the Olduvai Gorge. Trading contacts between Arabia and the East African coast existed by the 1st century AD, and there are indications of connections with India. The coastal trading centres were mainly Arab settlements, and relations between the Arabs and their African neighbours appear to have been fairly friendly. After the arrival of the Portuguese in the late 15th century, the position of the Arabs was gradually undermined, but the Portuguese made little attempt to penetrate into the interior. They lost their foothold north of the Ruvuma River early in the 18th century as a result of an alliance between the coastal Arabs and the ruler of Muscat on the Arabian Peninsula. This link remained extremely tenuous, however, until French interest in the slave trade from the ancient town of Kilwa, on the Tanganyikan coast, revived the trade in 1776. Attention by the French also aroused the sultan of Muscat's interest in the economic possibilities of the East African coast, and a new Omani governor was appointed at Kilwa. For some time most of the slaves came from the Kilwa hinterland, and until the 19th century such contacts as existed between the coast and the interior were due mainly to African caravans from the interior.

Early trade on the coast

In their constant search for slaves, Arab traders began to penetrate farther into the interior, more particularly in the southeast toward Lake Nyasa. Farther north two merchants from India followed the tribal trade routes to reach the country of the Nyamwezi about 1825. Along this route ivory appears to have been as great an attraction as slaves, and Sa'īd ibn Sulṭān himself, after the transfer of his capital from Muscat to Zanzibar, gave every encouragement to the Arabs to pursue these trading possibilities. From the Nyamwezi country the Arabs pressed on to Lake Tanganyika in the early 1840s. Tabora (or Kazé, as it was then called) and Ujiji, on Lake Tanganyika, became important trading centres, and a number of Arabs made their homes there. They did not annex these territories but occasionally ejected hostile chieftains. Mirambo, an African chief who built for himself a temporary empire to the west of Tabora in the 1860s and '70s, effectively blocked the Arab trade routes when they refused to pay him tribute. His empire was purely a personal one, however, and collapsed on his death in 1884.

The first Europeans to show an interest in Tanganyika in the 19th century were missionaries of the Church Missionary Society, Johann Ludwig Krapf and Johannes Rebmann, who in the late 1840s reached Kilimanjaro. It was a fellow missionary, Jakob Erhardt, whose famous "slug" map (showing, on Arab information, a vast, shapeless, inland lake) helped stimulate the interest of the British explorers Richard Burton and John Hanning Speke. They traveled from Bagamoyo to Lake Tanganyika in 1857–58, and Speke also saw Lake Victoria. This expedition was followed by Speke's second journey, in 1860, in the company of J.A. Grant, to justify the former's claim that the Nile rose in Lake Victoria. These primarily geographic explorations were followed by the activities of David Livingstone, who in 1866 set out on his last journey for Lake Nyasa. Livingstone's object was to expose the horrors of the slave trade and, by opening up legitimate trade with the interior, to destroy the slave trade at its roots. Livingstone's journey led to the later expeditions of H.M. Stanley and V.L. Cameron. Spurred on by Livingstone's work and example, a number of missionary societies began to take an interest in East Africa after 1860.

David Livingstone

German East Africa. It was left to Germany, with its newly awakened interest in colonial expansion, to open up the country to European influences. The first agent of German imperialism was Carl Peters, who, with Joachim, Count Pfeil and Karl Juhlke, evaded the sultan of Zanzibar late in 1884 to land on the mainland. He made a number of "contracts" in the Usambara area by which several chiefs were said to have surrendered their territory to him. Peters' activities were confirmed by Bismarck. By the Anglo-German Agreement of 1886 the sultan of Zanzibar's vaguely substantiated claims to dominion on the mainland were limited to a 10-mile-wide coastal strip, and Britain and Germany divided the hinterland between them as spheres of influence, the region to the south becoming known as German East Africa. Following the example of the British to the north, the Germans obtained a lease of the coastal strip from the sultan in 1888, but their tactlessness and fear of commercial competition led to a Muslim rising in August 1888. The rebellion was put down only after the intervention of the imperial German government and with the assistance of the British navy.

Recognizing the administrative inability of the German East Africa Company, which had theretofore ruled the country, the German government declared a protectorate over its sphere of influence in 1891 and over the coastal strip, where the company had bought out the sultan's rights. Germany was anxious to exploit the resources of its new dependency, but lack of communications at first restricted development to the coastal area. The introduction of sisal from Florida in 1892 by the German agronomist Richard Hindorff marked the beginning of the territory's most valuable industry, which was encouraged by the development of a railway from the new capital of Dar es Salaam to Lake Tanganyika. In 1896 work began on the construction of a railway running northeastward from Tanga to Moshi, which it reached in 1912. This successfully encouraged the pioneer coffee-growing activities on the slopes of Kilimanjaro. Wild rubber tapped by Africans, together with plantation-grown rubber, helped swell the country's economy. The government also supplied good-quality cottonseed free to African growers and sold it cheaply to European planters. The administration tried to make good the lack of clerks and minor craftsmen by encouraging the development of schools, an activity in which various missionary societies were already engaged.

Resistance to German rule

The enforcement of German overlordship was strongly resisted, but control was established by the beginning of the 20th century. Almost at once came a reaction to German methods of administration, the outbreak of the Maji Maji rising in 1905. Although there was little organization behind it, the rising spread over a considerable portion of southeastern Tanganyika and was not finally suppressed until 1907. It led to a reappraisal of German policy in East Africa. The imperial government had attempted to protect African land rights in 1895 but had failed in its objective in the Kilimanjaro area. Similarly, liberal labour legislation had not been properly implemented. The German government set up a separate Colonial Department in 1907, and more money was invested in East Africa. A more liberal form of administration rapidly replaced the previous semimilitary system.

World War I put an end to all German experiments. Blockaded by the British navy, the country could neither export produce nor get help from Germany. The British advance into German territory continued steadily from 1916 until the whole country was eventually occupied. The effects of the war upon Germany's achievements in East Africa were disastrous; the administration and economy were completely disrupted. In these circumstances the Africans reverted to their old social systems and their old form of subsistence farming. Under the Treaty of Versailles (1919), Britain received a League of Nations mandate to administer the territory except for Ruanda-Urundi, which came under Belgian administration, and the Kionga triangle, which went to Portugal.

Tanganyika Territory. Sir Horace Byatt, administrator of the captured territory and, from 1920 to 1924, first British governor and commander in chief of Tanganyika Territory (as it was then renamed), enforced a period of recuperation before new development plans were set on foot. A Land Ordinance (1923) ensured that African land rights were secure. Sir Donald Cameron, governor from 1925 to 1931, infused a new vigour into the country. He reorganized the system of native administration by the Native Authority Ordinance (1926) and the Native Courts Ordinance (1929). His object was to build up local government on the basis of traditional authorities, an aim that he pursued with doctrinaire enthusiasm and success. He attempted to silence the criticisms by Europeans that had been leveled against his predecessor by urging the creation of a Legislative Council in 1926 with a reasonable number of nonofficial members, both European and Asian. In his campaign to develop the country's economy, Cameron won a victory over opposition from Kenya by gaining the British government's approval for an extension of the Central Railway Line from Tabora to Mwanza (1928). His attitude toward European settlers was determined by their potential contribution to the country's economy. He was, therefore, surprised by the British government's reluctance to permit settlement in Tanganyika. The economic depression after 1929 resulted in the curtailment of many of Cameron's development proposals. In the 1930s, too, Tanganyika was hampered by fears that it might he handed back to Germany in response to Hitler's demands for overseas possessions.

Economic development

At the outbreak of World War II Tanganyika's main task was to make itself as independent as possible of imported goods. Inevitably the retrenchment evident in the 1930s became still more severe, and, while prices for primary products soared, the value of money depreciated proportionately. Tanganyika's main objective after the war was to ensure that its program for economic recovery and development should go ahead. The continuing demand for primary produce strengthened the country's financial position. The chief item in the development program was a plan to devote 3 million acres (1.2 million hectares) of land to the production of peanuts (the Groundnuts Scheme). The plan, which was to be financed by the British government, was to cost £25 million, and, in addition, a further £4.5 million would be required for the construction of a railway in southern Tanganyika. It failed because of the lack of adequate preliminary investigations and was subsequently carried out on a greatly reduced scale.

Constitutionally, the most important immediate postwar development was the British government's decision to place Tanganyika under UN trusteeship (1947). Under the terms of the trusteeship agreement, Britain was called upon to develop the political life of the territory, which, however, only gradually began to take shape in the 1950s with the growth of the Tanganyika African National Union (TANU). The first two African members had been nominated to the Legislative Council in December 1945. This number was subsequently increased to four, with three Asian nonofficial members and four Europeans. An official majority was retained. In an important advance in 1955, the three races were given parity of representation on the unofficial side of the council with 10 nominated members each, and for a time it seemed as if this basis would persist. The first elections to the unofficial side of the council, however, enabled TANU to show its strength, for even among the European and Asian candidates only those supported by TANU were elected.

A constitutional committee in 1959 unanimously recommended that after the elections in 1960 a large majority of the members of both sides of the council should be Africans and that elected members should form the basis of the government. The approval of the British colonial secretary was obtained for these proposals in December 1959, and in September 1960 a predominantly TANU government took office. The emergence of this party and its triumph over the political apathy of the people were largely due to the leadership of Julius Nyerere. Tanganyika became independent on Dec. 9, 1961, with Nyerere as its first prime minister.

Zanzibar. The history of Zanzibar has been to a large extent shaped by the monsoons (prevailing trade winds) and by its proximity to the continent. The regular annual recurrence of the monsoons has made possible its close connection with India and the countries bordering the Red Sea and the Persian Gulf. Its proximity to the continent has made it a suitable jumping-off point for trading and exploring ventures not only along the coast but also into the interior.

Contact with Islāmic states

Portuguese and Omani domination. Though the first references to Zanzibar occur only after the rise of Islām, there would appear to be little doubt that its close connection with southern Arabia and the countries bordering the Persian Gulf began before the Christian era. At the beginning of the 13th century, the Arab geographer Yakut recorded that the people of Lenguja (namely, Unguja, the Swahili name for Zanzibar) had taken refuge from their enemies on Tumbatu, the inhabitants of which were Muslims.

In 1498 Vasco da Gama visited Malindi, and in 1503 Zanzibar Island was attacked and made tributary by the Portuguese. It appears to have remained in that condition for about a quarter of a century. Thereafter the relations between the rulers of Zanzibar and the Portuguese seem to have been those of allies, the people of Zanzibar more

than once cooperating with the Portuguese in attacks upon Mombasa. In 1571 the "king" of Zanzibar, in gratitude for Portuguese assistance in expelling certain African invaders, donated the island to his allies, but the donation was never implemented. A Portuguese trading factory and an Augustinian mission were established on the site of the modern city of Zanzibar, and a few Portuguese appear also to have settled as farmers in different parts of the island. The first English ship to visit Zanzibar (1591–92) was the *Edward Bonaventure*, captained by Sir James Lancaster.

When the Arabs captured Mombasa in 1698, all these settlements were abandoned and (except for a brief Portuguese reoccupation in 1728) Zanzibar and Pemba came under the domination of the Arab rulers of Oman. For more than a century those rulers left the government of Zanzibar to local hakims (governors). The first sultan to take up residence in Zanzibar was Sayyid Sa'īd ibn Sulṭān, who after several short visits settled there soon after 1830 and subsequently greatly extended his influence along the East African coast. On Sa'īd's death in 1856 his son Majid succeeded to his African dominions, while another son, Thuwayn, succeeded to Oman.

As a result of an award made in 1860 by Lord Canning, governor general of India, the former African dominions of Sa'īd were declared to be independent of Oman. Majīd died in 1870 and was succeeded by his brother Barghash. Toward the end of the latter's reign his claims to dominion on the mainland were restricted by Britain, France, and Germany to a 10-mile-wide coastal strip, the administration of which was subsequently shared by Germany and Britain. Barghash died in 1888. Both he and Majīd had acted largely under the influence of Sir John Kirk, who was British consular representative at Zanzibar from 1866 to 1887. It was by Kirk's efforts that Barghash consented in 1873 to a treaty for the suppression of the slave trade.

British protectorate. In 1890 what was left of the sultanate was proclaimed a British protectorate, and in 1891 a constitutional government was instituted under British auspices, with Sir Lloyd Mathews as first minister. In August 1896, on the death of the ruling sultan, Ḥamad ibn Thuwayn, the royal palace at Zanzibar was seized by Khālid, a son of Sultan Barghash, who proclaimed himself sultan. The British government disapproved, and, as he refused to submit, the palace was bombarded by British warships. Khālid escaped and took refuge at the German consulate, whence he was conveyed to German East Africa. Ḥamud ibn Moḥammed was then installed as sultan (Aug. 27, 1896). In 1897 the legal status of slavery was finally abolished. In 1913 the control of the protectorate passed from the Foreign Office to the Colonial Office, when the posts of consul general and first minister were merged into that of British resident. At the same time, a Protectorate Council was constituted as an advisory body. In 1926 the advisory council was replaced by nominated executive and legislative councils.

Enforcement of British rule

Khalīfa ibn Harūb became sultan in 1911. He was the leading Muslim prince in East Africa, and his moderating influence did much to steady Muslim opinion in that part of Africa at times of political crisis, especially during the two world wars. He died on Oct. 9, 1960, and was succeeded by his eldest son, Sir Abdullah ibn Khalīfa.

In November 1960 the British Parliament approved a new constitution for Zanzibar. The first elections to the Legislative Council then established were held in January 1961 and ended in a deadlock. Further elections, held in June, were marked by serious rioting and heavy casualties. Ten seats were won by the Afro-Shirazi Party (ASP), representing mainly the African population; 10 by the Zanzibar Nationalist Party (ZNP), representing mainly the Zanzibari Arabs; and 3 by the Zanzibar and Pemba People's Party (ZPPP), an offshoot of the ZNP. The ZNP and ZPPP combined to form a government with Mohammed Shamte Hamadi as chief minister.

A constitutional conference held in London in 1962 was unable to fix a date for the introduction of internal self-government or for independence, because of failure to agree on franchise qualifications, the number of elected seats in the legislature, and the timing of the elections. An independent commission, however, subsequently delimited new constituencies and recommended an increase in the numbers of the Legislative Council, which the council accepted, also agreeing to the introduction of universal adult suffrage. Internal self-government was established in June 1963, and elections held the following month resulted in a victory for the ZNP–ZPPP coalition, which won 18 seats, the ASP winning the remaining 13. Final arrangements for independence were made at a conference in London in September. In October it was agreed that the Kenya coastal strip—a territory that extended 10 miles inland along the Kenya coast from the Tanganyika frontier to Kipini and that had long been administered by Kenya although nominally under the sovereignty of Zanzibar—would become an integral part of Kenya on that country's attainment of independence.

Independence. On Dec. 10, 1963, Zanzibar achieved independence as a member of the Commonwealth. In January 1964 the Zanzibar government was overthrown by an internal revolution, Sayyid Jamshid ibn Abdullah (who had succeeded to the sultanate in July 1963 on his father's death) was deposed, and a republic was proclaimed.

Although the revolution was carried out by only about 600 armed men under the leadership of the communist-trained "field marshal" John Okello, it won considerable support from the African population. Thousands of Arabs were massacred in riots, and thousands more fled the island. Sheikh Abeid Amani Karume, leader of the Afro-Shirazi Party, was installed as president of the People's Republic of Zanzibar and Pemba. Sheikh Abdulla Kassim Hanga was appointed prime minister, and Abdul Raḥman Mohammed ("Babu"), leader of the new left-wing Umma (The Masses) Party (formed by defectors from the ZNP), became minister for defense and external affairs. Pending the establishment of a new constitution, the cabinet and all government departments were placed under the control of a Revolutionary Council of 30 members, which was also vested with temporary legislative powers. Zanzibar was proclaimed a one-party state. Measures taken by the new government included the nationalization of all land, with further powers to confiscate any immovable property without compensation except in cases of undue hardship.

Revolt against Arab rule

The United Republic. The Tanganyikan constitution was amended in 1962, and Julius Nyerere became executive president of the Republic of Tanganyika. In 1963 TANU was declared the only legal party, but voters in each constituency were often offered a choice between more than one TANU candidate in parliamentary elections. That this arrangement amounted to something more than lip service to the idea of democracy was demonstrated in 1965 and in subsequent elections when, although Nyerere was reelected again and again as the sole candidate for president, a considerable number of legislators, including cabinet ministers, lost their seats.

An army mutiny was suppressed in January 1964 only after the president had reluctantly sought the assistance of British marines. Nyerere's authority was quickly restored, however, and in April he made an agreement with President Karume of Zanzibar to establish the United Republic of Tanzania, with Nyerere himself as president and Karume as first vice president. (Despite unification, for years Zanzibar continued to pursue its own policies, paying little attention to mainland practices.)

Nyerere's chief external task was to convince the outside world, particularly the Western powers, that Tanzania's foreign policy was to be one of nonalignment; but the overt involvement of the Eastern bloc in Zanzibar, as well as Nyerere's own insistence that to rectify the imbalance created in the colonial era Tanzania must turn more to the East for aid, did little to make the task easier. The high moral tone taken by the president over Britain's role in Rhodesia and over the supply of British arms to South Africa also strained the bonds of friendship between the two countries, with Tanzania severing diplomatic relations with Britain from 1965 to 1968. The consequent loss of aid from Britain was more than made good by help from Eastern countries, notably from China, which culminated in 1970 in the offer of an interest-free Chinese loan to finance the construction of a railway line linking Dar es Salaam with Zambia.

Though Nyerere fully appreciated the generous assistance his country was receiving, he was anxious to impress upon his countrymen the need for maximum self-reliance. Political freedom, he insisted, was useless if the country was to be enslaved by foreign investors. His views were formulated in the Arusha Declaration of Feb. 5, 1967. The resources of the country, Nyerere said, were owned by the whole people and were held in trust for their descendants. The leaders must set an example by rejecting the perquisites of a capitalist system and should draw only one salary. Banks must be nationalized, though compensation would be given to shareholders; the same would apply to the more important commercial companies. Agriculture, however, was the key to development, and only greater productivity could hold at bay the spectre of poverty. To give a fillip to his argument, people were to be moved into cooperative villages where they could work together for their mutual benefit.

Nyerere's Arusha Declaration

Nyerere's exhortations did not arouse the enthusiasm for which he had hoped. Individuals resisted his plans for collectivization, and not even the majority of his supporters wholeheartedly adopted his moral stand. The cooperative village scheme failed, bringing additional pressure to bear upon an already desperately weak economy. The sisal industry, one of those nationalized, became badly run down by the mid-1970s because of inefficient management.

Nyerere's criticisms were not reserved for his own people, nor yet for the wealthy nations of the world. In 1968 he challenged the rules of the Organization of African Unity (OAU) by recognizing the secession of Biafra from Nigeria, and in 1975 he attacked the OAU for planning to hold its summit meeting in Uganda, where Idi Amin was acting with extreme cruelty. Relations with Kenya also deteriorated, and in 1977 the East African Community ceased to exist after the closure of the Kenyan border. Even more challenging to the OAU's policy of nonintervention in the affairs of member states was the attack launched against Uganda in January 1979 after Amin had invaded the northwestern corner of Tanzania in October 1978. The retention of Tanzanian troops in Uganda for several years after Amin's overthrow, together with Nyerere's long-standing friendship with Uganda's former president, Milton Obote, also led to strained relations with some of Uganda's leaders as well as arousing suspicions in Kenya. Elsewhere in Africa, however, Nyerere was able to play an authoritative role, notably in the negotiations leading to the independence of Zimbabwe and in the formation of an organization of African states to try to resist economic domination by South Africa. (K.In.)

Events in Zanzibar caused continuing concern for the mainland leadership. The arbitrary arrest and punishment of anyone believed to oppose the state gave rise to regret that the constitution of the joint republic prevented the mainland authorities from intervening in the island's affairs where questions of law and justice were involved. The failure to hold elections in Zanzibar also contrasted unfavourably with developments on the mainland. In April 1972 Karume was assassinated by members of the military. His successor, Aboud Jumbe, had been a leading member of Karume's government, and, while his policies did not differ markedly from those of Karume, they appeared to be moving gradually closer into line with mainland practices. The amalgamation of TANU and the ASP under the title of Revolutionary Party (Chama cha Mapinduzi; CCM) early in 1977 was a hopeful sign but was followed by demands for greater autonomy for Zanzibar. This trend was checked when Ali Hassan Mwinyi succeeded Jumbe in 1984 and became president of the joint republic after Nyerere resigned in November 1985; however, in the late 1980s dissent resurfaced in Zanzibar, culminating in the revelation in January 1993 that Zanzibar had joined the Organization of the Islāmic Conference. Criticism on the mainland forced its withdrawal later that year.

The Revolutionary Party

Mwinyi inherited an economy suffering from the country's lack of resources, the fall in world prices for Tanzanian produce, the rise in petroleum prices, and inefficient management. An acute shortage of food added still further to his problems. Though he promised to follow Nyerere's policy of self-reliance, Mwinyi soon concluded that his predecessor's resistance to foreign aid could no longer be sustained. In accepting an offer of assistance from the International Monetary Fund (IMF) in 1986, Mwinyi adopted some structural reforms and furthered the devaluation of the currency begun in 1984 by Nyerere, who also had denationalized the state-run sector of the sisal industry in 1985. Moreover, private enterprise had been allowed to take over other areas of business. In May 1992 the constitution was amended to provide for a multiparty political system, and in 1995 the first national elections under this system were held. Nyerere's forecast that freedom would impose a heavy burden on the country had been realized, but his program of maximum self-reliance had failed to provide an immediate remedy for his country's problems. (K.In./Ed.)

For later developments in the history of Tanzania, see the BRITANNICA BOOK OF THE YEAR.

Uganda

The landlocked and mostly rural Republic of Uganda lies across the Equator approximately between latitudes 4° N and 1° S and longitudes 30° E and 35° E. Covering a total area of 93,070 square miles (241,000 square kilometres), the country is roughly the size of its former colonial ruler, Great Britain. Its neighbours are The Sudan to the north, Kenya to the east, Tanzania and Rwanda to the south, and Zaire to the west. The capital city, Kampala, is built around seven hills not far from the shores of Lake Victoria, which forms part of the frontier with Kenya and Tanzania.

Uganda obtained formal independence on Oct. 10, 1962. Its borders, drawn in an artificial and arbitrary manner in the late 19th century, encompassed two essentially different types of society: the relatively centralized Bantu kingdoms of the south and the Nilotic and Sudanic "tribes without rulers" to the north. This split between north and south—aggravated by uneven development under the British, which favoured the south—set the stage for years of turmoil in the postcolonial era, when, under military rulers such as Idi Amin, Uganda was torn by tyranny and bloodshed. When the violence subsided in the 1980s, the country faced the task of rebuilding, so that, with its beautiful green landscape and fertile agriculture, it could once again become what Winston Churchill called "the pearl of Africa." (O.H.K.)

Split between north and south

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Most of Uganda is situated on part of the Central Plateau, an enormous monotonous expanse that drops gently from about 5,000 feet (1,500 metres) in the south to approximately 3,000 feet in the north. The limits of Uganda's plateau region are marked by mountains and valleys.

To the west a natural boundary is composed of the Virunga (Mufumbiro) Mountains, the Ruwenzori Range, and the Western Rift Valley. The volcanic Virunga Mountains rise to 13,540 feet at Mount Muhavura and include Mount Sabinio (11,960 feet), where the borders of Uganda, Zaire, and Rwanda meet. Farther north the Ruwenzori Range—popularly believed to be Ptolemy's Mountains of the Moon—rises to 16,795 feet at Margherita Peak; its heights are often hidden by clouds, and its peaks are capped by snow and glaciers. Between the Virunga and Ruwenzori mountains lie Lakes Edward and George. The rest of the boundary is composed of the Western Rift Valley, which contains Lake Albert and the Albert Nile River.

The northeastern border of the plateau is defined by a string of volcanic mountains, including Mounts Zulia (7,048 feet), Morungole (9,022 feet), Moroto (10,116 feet), and Kadam (Debasien; 10,067 feet). The southernmost mountain—Mount Elgon—is also the highest of the chain, reaching 14,178 feet. South and west of these mountains is an eastern extension of the Rift Valley, as well as Lake Victoria. To the north the plateau is marked on the Sudanese border by the Imatong Mountains, with an elevation of about 6,000 feet.

Drainage. The country's drainage system is dominated by six major lakes—Victoria (26,828 square miles), the

world's second largest inland freshwater lake (after Lake Superior in North America), to the southeast; Edward and George to the southwest; Albert to the west; Kyoga in central Uganda; and Bisina in the east. Together with the lakes, there are eight major rivers. These are the Victoria Nile in central Uganda; the Achwa, Dopeth-Okok, and Pager in the north; the Albert Nile in the northwest; and the Kafu, Katonga, and Mpongo in the west.

The Nile system

The southern rivers empty into Lake Victoria, the waters of which escape through Owen Falls near Jinja and form the Victoria Nile. This river flows northward through the eastern extension of Lake Kyoga. It then turns west and north to drop over Karuma Falls and Murchison (or Kabalega) Falls before emptying into Lake Albert.

Lake Albert is drained to the north by the Albert Nile, which is known as the Baḥr al-Jabal, or Mountain Nile, after it enters The Sudan at Nimule. Rivers that rise to the north of Lake Victoria flow into Lake Kyoga, while those that rise north of Kyoga tend to flow into the Albert Nile. The rivers of the southwest flow into Lakes George and Edward.

Except for the Victoria and Albert Niles, the rivers are sluggish and often swampy. Clear streams are found only in the mountains and on the slopes of the Rift Valley. Most of the rivers are seasonal and flow only during the wet season, and even the few permanent rivers are subject to seasonal changes in their rates of flow.

Soils. The soils are predominantly ferralites (soils containing iron and aluminum). Interspersed with these are the waterlogged clays characteristic of the northwest and of the western shores of Lake Victoria. In general the soils are fertile, although they are of poorer quality in the north than in the south.

Climate. With the equator passing through southern Uganda, the climate is characteristically tropical. Temperatures are modified, however, by elevation and, locally, by the presence of the lakes. The major air currents are northeasterly and southwesterly. There is little variation in the sun's declination at midday, and the length of daylight is nearly always 12 hours. All of these factors, combined with an equatorial cloud cover, ensure an equable climate throughout the year.

Most parts of Uganda receive adequate rainfall; amounts range from a low of less than 20 inches (500 millimetres) a year in the northeast to a high of 80 inches in the Sese Islands of Lake Victoria. In the south there are two wet seasons, occurring in April and May and in October and November, which are separated by dry periods broken by tropical thunderstorms. In the north the climate is roughly divided into a wet season from the months of April to October and a dry season that lasts from November to March.

Plant and animal life. Wooded savanna (grassy parkland) is typical of central and northern Uganda. Under less favourable conditions, dry acacia woodland, dotted with the occasional candelabra (tropical African shrubs or trees with huge spreading heads of foliage) and euphorbia (plants often resembling cacti and containing a milky juice) and interspersed with grassland, occurs in the south. Similar components are found in the vegetation of the Rift Valley floors. The steppes (treeless plains) and thickets of the northeast represent the driest regions of Uganda. In the Lake Victoria region and the western highlands, the mosaic of elephant grass and forest remnants appears to have resulted from human incursions affecting the former forest covering. The medium-elevation forests contain a rich variety of species, with many representatives of West African vegetation. The high-elevation forests of Mount Elgon and the Ruwenzori Range occur above 6,000 feet; on their upper margins they give way, through transitional zones of mixed bamboo and tree heath, to high mountain moorland. Uganda's 5,600 square miles of swamp include both papyrus swamp and seasonal, grassy swamp.

Remnants of forest

Lions and leopards are widely distributed but are seen only infrequently. Hippopotamuses and crocodiles inhabit most lakes and rivers, although the latter are not found in Lakes Edward and George. Mountain gorillas, chimpanzees, and small forest elephants occur only in the extreme west. Elephants, buffalo, and the Uganda kob (an antelope) are found in the west and north, while the black rhinoceros, white rhinoceros, and giraffe are confined to the north. Zebras, topis, elands, and roan antelopes occur both in the northeastern and southern grasslands, but other kinds of antelopes, such as the oryx, greater and lesser kudu, and Grant's gazelle, live only in the northeastern area. The varied fish life includes ngege (a freshwater, nest-building fish of the tilapia species) and Nile perch.

Insects are a significant element in the biological environment. The female anopheles mosquito may transmit malaria anywhere below 5,000 feet, and extensive areas of good grazing are closed to cattle because of the presence of deadly tsetse flies.

The three national parks contain an interesting variety of animal life. Murchison Falls (or Kabalega) National Park, with an area of 1,500 square miles, stretches on either side of the Victoria Nile. Queen Elizabeth (or Ruwenzori) National Park occupies some 850 square miles in the Lake Edward–Lake George basin, and Kidepo National Park consists of 480 square miles of magnificent country adjacent to the Sudanese frontier. (M.S.Ki.)

Settlement patterns. Uganda's population remains basically rural, although the urban population is growing at a faster rate. Virtually all of Uganda's cities and towns arose from the colonial experience. The capital, Kampala, is the largest, and the other major cities are Jinja, Mbale, Mbarara, Masaka, Entebbe, and Gulu. Apart from Gulu, all of these are located in the south, where centralized and hierarchical political communities, often led by a king, existed before colonization.

The growth of urban centres has been caused by a rural–urban migration within the south itself as well as from the north to southern towns. These towns resemble Western cities more than they do rural Uganda. Before independence, urban dwellers were mainly British and Asian immigrants; only gradually did a minority of black urbanites begin to emerge, and then Idi Amin's "economic war" of the 1970s expelled most immigrants, who were replaced by black Ugandans. Since then, an interesting consequence has been the "ruralization" or "villagization" of towns, as formerly open spaces and parks have been converted into private little gardens. To some extent, in some instances town and country have merged.

Surrounding most urban centres are "shantytowns," dirty, ugly, and crowded neighbourhoods inhabited by the very poor who have abandoned rural life and yet do not fit into the cities. These slums, whose inhabitants include informal petty traders, prostitutes, pimps, manual labourers, and pickpockets, are often breeding grounds for crime, violence, and disease.

The rural majority is as diverse as the number of Ugandan ethnic groups. However, they can be divided into two groups: the nomadic pastoral Ugandans and the relatively more sedentary farmers. These rural peoples are the custodians of Uganda's indigenous cultures, yet since 1900 modernization has been creeping in on them, too, as roads, electricity, piped water, and health-care centres have gradually reached the countryside. Historically, rural life has been kinship-based, with people living in intimate communities of broadly defined relatives, but the relative modernization and mechanization of agriculture, including the introduction of modern ranching and cash crops, have helped to transform rural life.

The people. *Ethnic groups.* Although Uganda is inhabited by a large variety of ethnic groups, a division is usually made between the "Nilotic North" and the "Bantu South." Bantu speakers represent over 70 percent of Uganda's population. Of these, the Ganda remain the largest single ethnic group, constituting about 20 percent of the total national population. In addition to the Ganda, other members of the so-called Eastern Lacustrine wing of the Bantu are the Soga, Gwe, Gisu, Nyole, Samia, and Kenyi. The Western Lacustrine branch includes the Nkole, Toro, Nyoro, Kiga, Amba, and Konjo.

"Nilotic North" and "Bantu South"

Like the Bantu South, the Nilotic North is often divided into western and eastern branches. The Western Nilotes represent approximately 15 percent of Uganda's population and are usually known collectively as the Luo. The Acholi and Lango are the two largest subgroups of this

category; smaller groups are the Alur, Padhola, Kumam, and Jonam. The Eastern Nilotes constitute approximately 12 percent of Uganda's population. Their four largest members are the Dodoth, Teso, Jie, and Karamojong; closely related is a variety of smaller groups including the Kakwa, Sebei, Labwor, Nyakwai, Tepeth, Napore, Nyangea, and Teuso. Also to be found in the north are Central Sudanic peoples, who include the Lendu, Lugbara, and Madi. Together they constitute about 6 percent of Uganda's population.

Under British colonial rule, economic power and education were concentrated in the south. As a result, the Bantu came to dominate modern Uganda, occupying most of the high academic, judicial, bureaucratic, and religious positions and a whole range of other prestigious roles. On the other hand, the armed forces created by the British recruited overwhelmingly from the north, and the police, paramilitary forces, and prisons were also dominated by northerners. This meant that, just as economic power lay in the south, military power was concentrated in the north. The political events of postcolonial Uganda have to a large extent been shaped by this imbalance.

By 1969 there were about 75,000 Indians, Pakistanis, and Bangladeshis in Uganda, most of whom lived in cities and towns and were primarily involved in commerce and trade. Although Ugandan citizenship was available to them, most Asians preferred to retain British passports. Since the sudden expulsion in 1972 by Idi Amin of all noncitizen Asians, the Asian population has almost disappeared from Uganda. Amin's action proved immensely popular with most indigenous Ugandans, but the country has yet to recover completely from the economic consequences of those swift expulsions.

In the 1960s Uganda also had approximately 10,000 resident western Europeans and North Americans, who served mostly in the professions. Most left the country around the time of the Asian deportations.

Languages. The language of official business in Uganda is English. Although only a tiny fraction of the populace speaks English well, access to high office, prestige, and economic and political power is almost impossible without an adequate command of this language. Swahili has been chosen as another official national language, and its potential for facilitating regional integration is immense. However, the command of Swahili by most Ugandans falls substantially below that of peoples in Tanzania, Kenya, and even eastern Zaire.

The major languages

Uganda's indigenous languages are coextensive with its different ethnic groups. Only the major native languages possess a sustained or extensive written tradition. In addition to English, French, Arabic, and Swahili, Radio Uganda broadcasts in the following indigenous languages: Alur, Ateso, Dhopadhola, Kakwa, Karamojong, Kumam, Kupsabiny, Luganda, Lugbara, Lugwe, Lumasaba, Lunyole, Luo, Lusamia, Lusoga, Madi, Rukiga, Rukonjo, Runyankole, Runyoro, and Rutoro. Most Ugandans can understand at least one of these.

Religions. Uganda has a triple religious heritage of indigenous religions, Islām, and Christianity. Reliable statistics are rare, but most figures suggest that the largest religious community is that of the Roman Catholics (about one-half of the population), followed by that of the Anglicans with one-quarter of the population and the Muslims with less than 10 percent.

Of the immigrant religions, Islām was the first to arrive, but its believers remain a small minority, and it was politically significant only under Amin. In the colonial period Uganda witnessed a spirited Christian missionary activity—especially in the south, where Catholics were called *bafaransa* ("the French") and Protestants *bangerezza* ("the British"). Rivalry and even hostility between adherents of these two branches of Christianity, which have always been sharper and deeper than those between Christians and Muslims, are still alive today.

Although the immigrant religions dominate official statistics, most knowledgeable observers agree that the numerous indigenous religions command the greatest number of adherents. This is because most Ugandans, even after converting to Islām or Christianity, do not abandon their traditional beliefs altogether but blend them with their adopted faiths.

Demographic trends. With an annual growth rate of about 3 percent, the doubling time for Uganda's population is only a little more than 20 years. As many as one-half of Ugandans are under 15 years of age.

Barely 10 percent of Ugandans reside in cities or towns. Of these centres the most important are Kampala, the political and commercial capital, where approximately 35 percent of Uganda's urban population is concentrated, and Jinja, the industrial capital. The most densely populated areas are in the south, especially around Lake Victoria and Mount Elgon.

Houses near Mount Muhavura, western Uganda.

The economy. The economy is basically agricultural, with Uganda's moderate climate congenial to the production of both livestock and crops.

As has been the case with most African countries, economic development and modernization have remained elusive—a predicament that has been exacerbated by the country's chronic civil wars and sometimes by drought. In order to repair the damage done to the economy under Idi Amin, the government has encouraged foreign investments in agriculture and core industries, mainly from Western countries and former Asian residents. Attempts have also been made to secure support and loans from the World Bank and the International Monetary Fund.

Agriculture. Agriculture accounts for more than 95 percent of Uganda's export earnings and half of the gross domestic product (GDP), and it is the main source of income for well over 90 percent of the adult population. More than half of agricultural production is done by subsistence farmers, the vast majority of whom are based in the south, where there is more rainfall and fertile soil. Small-scale mixed farming predominates. The two most important cash crops for export are coffee and cotton. Tea and sugar are also grown for export. Food crops include corn (maize), millet, sorghum, cassava, sweet potatoes, plantains, peanuts (groundnuts), and various vegetables.

Major crops

Industry. Industry contributes less than 10 percent of the GDP and employs a commensurate portion of the labour force. The major industries are in the processing of such agricultural products as tea, tobacco, sugar, coffee, cotton, animal feeds, grains, dairy products, and edible oils, in the brewing of beer, and in the manufacture of cement, fertilizers, matches, metal products, paints, shoes, soap, steel, textiles, and motor vehicles.

Because of a serious lack of technical and management

personnel, a scarcity of spare parts, machinery, and fuel, and not least because of the devastation of war, industrial production has declined immensely since the early 1970s. By contrast, from 1961 to 1970 industrial output grew by 7.8 percent annually. With the return of stability to the country, foreign companies and lending institutions have invested in textile and steel mills, a motor vehicle assembly plant, a tannery, bottling and brewing plants, and cement factories.

Finance. Uganda's central bank, the Bank of Uganda, was founded in 1966. It monitors Uganda's commercial banks, serves as the government's bank, and issues the national currency, the Uganda shilling. The government sets the shilling's official exchange rate against foreign currencies, but in the "parallel economy," or black market, it can be obtained for a fraction of its official value.

The Uganda Commercial Bank, the Uganda Cooperative Bank, and the Uganda Development Bank serve most of the commercial and financial needs of the country. There are also commercial banks owned by British, Indian, and Libyan firms.

Trade. Uganda's principal exports are coffee, tea, cotton, copper, and sugar. Skins and hides are also sold outside the country. Coffee alone accounts for more than 90 percent of Uganda's export earnings. The principal destinations are the United States, France, Germany, Spain, the United Kingdom, and Japan.

Uganda imports machinery and transport equipment, assorted manufactured goods (including various metal products), fuels, and foodstuffs. The principal sources of imports include Kenya and Tanzania, Germany, the United Kingdom, and India.

Transportation. Being a landlocked state, Uganda relies heavily on Kenya and Tanzania (particularly the former) for access to the sea. Linking Kampala with Kilindini Harbour at Mombasa in coastal Kenya is a rail line that passes via Jinja, Tororo, Leseru, Nakuru, and Naivasha. Kampala is also connected to the north by a rail line that traverses the Pakwach bridge and to the western parts of the country by a line that reaches the border town of Kasese.

The state-owned Uganda Airlines offers international as well as domestic flights. The main international airport is at Entebbe, Uganda's former capital, about 20 miles to the west of Kampala.

Less than one-fourth of Uganda's road system is paved. There are river services on the Kagera River and lake services on Lakes Albert and Victoria.

Administration and social conditions. *Government.* Until 1967 Uganda was a quasi-federal polity that included five subregional monarchies, nonmonarchical districts, and a central government. The republican constitution adopted in 1967 abolished the monarchies and assigned ultimate political power to an elected president. The president was to be aided by a ministerial cabinet drawn, in the British tradition, from among members of the unicameral National Assembly. In theory the judiciary, legislature, and executive were to be autonomous, if coordinate, institutions of governance, but in reality the powers of the different branches of government varied widely with each president. Under Idi Amin's presidency (1971–79), representative institutions were abolished altogether, and, with the first of several military coups d'état in 1985, the constitution was suspended. While a commission drafts a new constitution, power rests in the hands of the president. A legislature called the National Resistance Council is composed of members appointed by the president as well as members elected by district and county Resistance Committees. Political parties exist, but active campaigning during elections is forbidden.

The 1967 constitution

Uganda is divided into 10 provinces: Busoga, Eastern, Kampala, Karamoja, Nile, North Buganda, Northern, South Buganda, Southern, and Western. The president appoints the provincial governors, who in turn appoint commissioners to run the 33 districts.

Education. Many of the oldest schools in Uganda were established by Christian missionaries from Europe. Since independence their role has been superseded by that of the government, but, because the number of secondary schools is modest, mission schools remain an important component of Uganda's educational system.

Makerere University in Kampala, which began as a secondary school in the 1920s, was the first major institution of higher learning in East and Central Africa. In addition to its medical school, Makerere's faculties include those of agriculture, arts, education, engineering, law, science, social sciences, and veterinary science. Other institutions previously affiliated to Makerere are the Institute of Teachers' Education and the National College of Business Studies.

Health. The vast majority of Uganda's hospitals are government-operated, the remainder being run by private charitable organizations.

The major killer diseases are malaria, measles, sleeping sickness, venereal diseases, shigellosis (dysenterial infections), whooping cough, hookworm, poliomyelitis, schistosomiasis, yaws, smallpox, tuberculosis, chicken pox, typhoid, and leprosy. Unclean water is a major carrier of these diseases. AIDS (acquired immune deficiency syndrome), known locally as "slim" because of its debilitating effects, is spreading at an alarming rate, with fully 10 percent of all adults said to be infected with the AIDS virus.

In the late 1980s the infant mortality rate per 1,000 live births was 103. Average life expectancy was 49 years for men and 53 years for women. Besides disease, the death rate in Uganda has been affected by years of anarchy, tyranny, economic dislocation, and the disintegration of government medical services.

Cultural life. *Daily life.* In spite of Uganda's ethnic diversity, virtually all communities are both patriarchal (male-dominated politically) and patrilineal (with descent traced through the father). Polygyny is widespread, while polyandry is unheard of. Being basically a rural people, most Ugandans, male and female, spend their daily lives working the land. Most children now go to school, but where a family choice must be made about which child to educate, it is often the son and rarely the daughter who is favoured.

Ugandan foods

The staple diet in most of the south is a kind of plantain called *matoke*. Often sweet potatoes and cassava, too, are consumed. The bulk of the north consumes millet, sorghum, cornmeal, and cassava. The pastoralist communities tend to consume animal-derived products, especially butter, meat, and animal blood. Fish is eaten throughout the country by all groups.

The most popular sport by far is association football (soccer). Other popular sports and games include boxing, wrestling, basketball, field hockey, rugby, athletics (track and field), netball, and golf.

The arts. The Westernized elites are virtually the sole consumers and practitioners of the fine arts. However, indigenous music remains popular and is widely broadcast by Radio Uganda and Uganda Television. The most popular foreign tunes are Zairean and Western music. Most nightclubs and dance halls often combine all of these musical traditions.

In precolonial times there were no individual works of art, since creativity tended to be basically collective and cumulative. Under European influence, however, Uganda now has developed well-known individual musicians, dancers, writers, actors, and other artists.

Uganda has nine museums, the largest and most important being the Uganda Museum in Kampala. Other museums include those at Murchison Falls and Queen Elizabeth national parks. The National Theatre is based in Kampala, while a wide variety of smaller theatres exist across the country.

The news media. Radio Uganda is government-owned, as is Uganda Television. Television is transmitted over a radius of 200 miles from Kampala, and there are relay stations around the country.

A fluctuating range of daily newspapers is published in Uganda, all of them in Kampala. Daily newspapers published in English include *Telecast*, *The Star*, and the state-owned *New Vision*. There are also three dailies in Luganda (*Taifa Empya*, *Munno*, and *Ngabo*) and various weeklies, periodicals, and assorted papers in both English and Luganda.

The degree of governmental control and censorship of the press has varied under different regimes, but, as elsewhere in the Third World, a completely free and independent press has never existed in Uganda. (O.H.K.)

For statistical data on the land and people of Uganda, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

There are no written records for the history of Uganda dating back much before the mid-19th century. For some centuries before that, however, Nilotic and Nilo-Hamitic tribes had been migrating southward into the area of Lake Victoria, where they had blended with or superimposed themselves upon the Bantu inhabitants. Possibly in the 15th century a race of tall, fair-skinned, and finely featured Hima people, cattle keepers, moved into what is now western Uganda and became the overlords of the area, treating as servants the agricultural peasantry who inhabited the country before them. This invasion was followed by another wave, this time of Nilotes, from around the Al-Ghazāl River in the Sudan. These latter, as they crossed the Nile, pushed the earlier invaders before them. Their advance guard settled in western Uganda and established the state of Bunyoro-Kitara. Other offshoots of the same movement settled in Acholi, while some recrossed the Nile northward to make their homes for a time in what is now Lango district. The advance of the Lango themselves forced the earlier migrants to resume their journey eastward and southward until they finally took up their residence on the northeastern shore of Lake Victoria in the present Nyanza region of Kenya. This move took place only in the 19th century, for the Lango, Teso, and other Nilo-Hamitic groups who began to move into what is now northern Uganda toward the end of the 17th century seem to have halted in their advance for almost 100 years and recommenced their southward march to the Nile only toward the end of the 18th century.

Nilotic invasion

Bunyoro and Buganda. The organization of the tribes who came to inhabit the area north of the Nile was mainly based upon their clan structure. In this respect the northern tribes differed markedly from the peoples to the southwest of the Nile, where the dominant state was that of Bunyoro-Kitara, which, under able rulers, extended its influence eastward and southward over a considerable area. To the south there were a number of lesser Hima states, each with its chief, who, like the ruler of Bunyoro-Kitara, combined priestly functions with those of a secular leader. To the southeast of Bunyoro-Kitara the smaller state of Buganda grew up as an offshoot of its larger neighbour. By the end of the 18th century, however, the boundaries of Bunyoro-Kitara had been stretched so far that the authority of the ruler began to crumble, and a succession of pacific chiefs accelerated this decline. Simultaneously the smaller, more compact state of Buganda enjoyed a succession of able and aggressive kabakas, or rulers, and began to expand at the expense of Bunyoro-Kitara.

It was during this period of Buganda's rise that the first Arab traders reached the country in the 1840s. Their object was to trade in ivory and slaves. Mutesa I, who took office about 1856, admitted the first European explorer, Captain John Hanning Speke, who crossed into the kabaka's territory in 1862. Speke was not impressed by Mutesa, whom he regarded as an arrogant youth.

Henry Morton Stanley, who reached Buganda in 1875, found Mutesa a more mature man. Experience and the dangers facing his country had mellowed his character. Although Buganda had not been attacked, Acholiland, to the north, had been ravaged by slavers from Egypt and the Sudan since the early 1860s, and, on the death of Kamrasi, the ruler of Bunyoro, his successor, Kabarega, had defeated his rivals only with the aid of the slavers' guns. Moreover, an emissary from the Egyptian government, Linant de Bellefonds, had reached Mutesa's headquarters just before Stanley, so that the kabaka was anxious to obtain allies. He readily agreed to Stanley's proposal to ask Christian missionaries to go to Uganda but was disappointed, when the first agents of the Church Missionary Society arrived in 1877, to find that they had no interest in military matters.

Christian missions

In 1879, representatives of the Roman Catholic White Fathers Mission also reached Buganda, and Mutesa was shrewd and strong enough to ensure that the missionaries did not stray far from his headquarters. Nonetheless, their influence rapidly increased because they were in constant touch with the chiefs whom the kabaka kept around him, and inevitably they became drawn into the politics of the country. Mutesa himself had little to fear from these new influences, and when, owing to the Mahdist rising in the Sudan, Egyptian expansion was checked, he felt confident in dealing brusquely with the handful of missionaries in his country. His successor, Mwanga, who became kabaka in 1884, was a weaker character and soon became jealous of their influence. Attempting to drive the missionaries and their supporters from the country, he was himself deposed in 1888, only to be followed soon after by his intended victims, who had been forced to flee by Muslim Ganda, whose numbers had grown under Arab influence.

The Uganda Protectorate. Mwanga's restoration with the assistance of the Christian Ganda, both Roman Catholic and Protestant, coincided with the first contact of European imperialism with Buganda. The German adventurer Carl Peters made a treaty of protection with Mwanga in 1889, but this was revoked when the Anglo-German agreement of 1890 declared all the country north of latitude 1° S to be a British sphere of influence. The Imperial British East Africa Company agreed to administer the region on behalf of the British government, and in 1890 the company's agent, Captain F.D. Lugard, made a treaty with Mwanga, placing Buganda under the company's protection. Lugard also made treaties of protection with two other chiefs, the rulers of the western states of Ankole and Toro. Shortage of money soon forced the company to abandon its charge, however, and, partly for strategic reasons and partly as a result of pressure from missionary sympathizers in Britain, the British government itself declared a protectorate over Buganda in 1894.

The government inherited from the company a country divided into politico-religious factions that, in Lugard's time, had even erupted into civil war (1892). Buganda was also threatened by Kabarega, the ruler of Bunyoro, but an expedition against him in 1894 deprived him of his headquarters and made him a refugee for the rest of his career in Uganda. The protectorate was extended in 1896 to include Bunyoro, Toro, Ankole, and Busoga, and in the later 1890s treaties were also made with chiefs to the north of the Nile. Mwanga revolted against British overlordship in 1897 and was overthrown and replaced by his infant son.

A mutiny of the administration's Sudanese troops in 1897 roused the British government to take a more active interest in the Uganda protectorate, and in 1899 Sir Harry Johnston was commissioned to visit the country and to make recommendations on its future administration. The main outcome of his mission was the Buganda Agreement of 1900, which formed the basis of British relations with Buganda for more than 50 years. Under its terms the kabaka was recognized as ruler of Buganda as long as he remained faithful to the protecting authority. His council of chiefs, the *lukiko,* was given statutory recognition. It was the leading chiefs who benefited most from the agreement, since in addition to the greater authority that they acquired, they were also granted land in freehold to ensure their support for the negotiations. Johnston made another agreement of a less detailed nature with the ruler of Toro (1900), and subsequently a third agreement was made with the ruler of Ankole (1901). Meanwhile British administration was being gradually extended north and east of the Nile, but in these areas, where a centralized authority was unknown, no agreements were made and British officers, frequently assisted by Buganda agents, administered the country directly. By 1914 Uganda's boundaries had been fixed and administration had reached most areas.

The Buganda Agreement of 1900

Growth of a peasant economy. Early in the 20th century Sir James Hayes Sadler, who succeeded Johnston as commissioner, concluded that the country was unlikely to prove attractive to European settlers. Sadler's own successor, Sir Hesketh Bell, turned this practical observation into a dogma and announced that he wished to develop Uganda

as an African state. In this he was opposed by a number of his more senior officials and in particular by the chief justice, William Morris Carter. Carter was chairman of a land commission whose activities continued until after World War I. Again and again the commission urged that provision be made for European planters, but their efforts were unsuccessful. Bell himself had laid the foundations of a peasant economy by encouraging the cultivation of cotton, which had been introduced into the country as an economic crop in 1904. It was mainly owing to the wealth derived from cotton that Uganda became independent of a grant-in-aid from the British Treasury in 1914.

Although there were a few skirmishes on the southwestern frontier in 1914, Uganda was never in danger of invasion, but World War I did retard the country's development. Soon after the war it was decided that the protectorate authorities should concentrate, as Bell had suggested, upon encouraging African agriculture. This policy was made necessary by the British government's decision to forbid the alienation of land in freehold; and the depression of the early 1920s dealt a further blow to the hopes of European planters. Henceforward, plantation-grown coffee, though second in importance to cotton for the time being, never threatened the supremacy of Uganda's chief product. The part to be played by Europeans as well as Asians was now mainly on the commercial and processing side of the protectorate's agricultural industry. When an additional crop was sought in order to widen the basis of the economy, it was African-grown coffee that the agricultural department encouraged.

The increased output of primary produce called for a considerable extension and improvement in communications. Just before World War I a railway had been built running northward from Jinja, on Lake Victoria, to Namasagali, with a view to opening up the Eastern Province. In the 1920s the railway from Mombasa, on the Kenyan coast, was extended to Soroti, and in 1931 a rail link was also completed between Kampala, the industrial capital of Uganda, and the coast.

Rail link to the Kenyan coast

The depression of the early 1930s caused a halt in Uganda's economic progress, but the protectorate's recovery was more rapid than that of its neighbours, so that the later 1930s were a period of steady expansion.

Political and administrative development. In 1921 a Legislative Council was instituted, but its membership was so small (four official and two nonofficial members) that it made little impact upon the country. The Indian community, which played an important part in the commercial life of the protectorate, was resentful to find that it was not to have equal representation with Europeans on the unofficial side of the council and so refused to participate until 1926. There was no evidence of a desire on the part of the Africans to sit in the council, since the most politically advanced section of the community, the Ganda, regarded its own *lukiko* as the most important council in the country.

In view of this attitude on the part of the Africans toward the protectorate legislature, it is not surprising that they opposed the suggestion, current in the later 1920s, that there should be some form of closer union between the East African territories. It was not only an interest in tribal traditions but also a fear of domination by Kenya's European settlers that stimulated this opposition. The Europeans of the protectorate also resented what they regarded as the subordinate character of Uganda's relations with Kenya, while the Asians were as worried as the Africans about the possible supremacy of Kenya's white settlers.

Perhaps the main feature in local government between the wars was the gradual replacement of older chiefs, men of strong personality but usually lacking a formal education, by younger, better educated men, more capable of carrying out the protectorate administration's policy and more amenable to British control. In Buganda, too, the protectorate administration began to interfere more actively in the kingdom's affairs in order to increase efficiency. The main result was to lessen the respect shown by the people to the chiefs outside Buganda and to cause resentment on the part of some of the Ganda chiefs against the insidious curtailment of their powers. Another important development was the beginning of government interest in education. Missionary societies had opened a number of good schools in Buganda. In 1925 an education department was set up by the protectorate administration, and, while aid was given to the missionary societies, government schools were also opened.

World War II and its aftermath. In World War II Uganda was faced with the task of becoming as self-sufficient as it could. More important than the actual military struggle as far as Uganda was concerned, however, was an attempt by the governor, Sir Charles Dundas, to reverse his predecessors' policy and to give more freedom to the factions striving for power in Buganda. After an outbreak of rioting in 1945, however, the old policy was revived. In 1945, too, the first Africans were nominated to the Legislative Council, and in succeeding years there was a steady increase in African representation. An important step was taken in 1954 when the African membership of the council was increased to 14 out of a total of 28 nonofficial members; the 14 were selected to represent districts thought to be more natural units of representation than the provinces that had previously been represented. In 1955 a ministerial system was introduced, with 5 nonofficial ministers out of a total of 11. The success of the council was undermined, however, by Buganda's erratic participation, since a central legislature was thought to threaten the degree of autonomy that Buganda enjoyed. This feeling was strengthened by the deportation in 1953 of Mutesa II, the kabaka, for refusing to cooperate with the protectorate government. He returned in 1955 as a constitutional ruler, but the rapprochement between Buganda and the protectorate government was lukewarm.

Africans on the Legislative Council

In the immediate postwar years the protectorate administration placed greater emphasis upon economic and social development than upon political advance. From 1952 there was a rapid increase in government provision for secondary education, while legislation was enacted and a loan fund established to encourage Africans to participate in trade. A relatively ambitious development program was greatly assisted by the high prices realized for cotton and for coffee, which overtook cotton as Uganda's most valuable export in 1957. In 1954 a large hydroelectric project was inaugurated at Owen Falls on the Nile near Jinja, and in 1962 a five-year development plan was announced.

The Republic of Uganda. In the late 1950s, with the emergence of a few political parties, the attention of the African population was concentrated on achieving self-government, though, owing to the poor organization of the parties and the fact that they were based upon Buganda, the focus of interest remained in the Legislative Council, where the other parts of the country felt themselves to be better represented. The kingdom of Buganda intermittently pressed for independence from Uganda, and the question of the protectorate's future status became acute. Discussions in London in 1961 led to full internal self-government in March 1962. Benedicto Kiwanuka, a Roman Catholic Ganda who was formerly chief minister, became the first prime minister, but in the elections in April 1962 he was displaced by Milton Obote, a Lango who headed the Uganda People's Congress party (UPC). At further discussions in London in June 1962, it was agreed that Buganda should receive a wide degree of autonomy within a federal relationship. Faced with the emergence of Obote's UPC, which claimed support throughout the country apart from Buganda, and of the Democratic Party (DP), which was based in Buganda and led by Kiwanuka, conservative Ganda leaders set up their own rival organization, Kabaka Yekka (KY), "King Alone."

Obote's first presidency. Divided politically on a geographic as well as an ethnic basis, Uganda became independent on Oct. 9, 1962. By accepting a constitution that conceded what amounted to federal status to Buganda, Obote contrived an unlikely alliance with the Ganda establishment. Together the UPC and KY were able to form a government with Obote as prime minister and with the DP in opposition. In an attempt to weld the alliance more firmly, Obote agreed to the appointment of Mutesa II as the country's first president, replacing the British governor-general. The move was unsuccessful. Although

Conflict between prime minister and kabaka

Obote was able to win over some of the members of the KY and even of the DP so that they joined the UPC, tension between the kabaka on the one hand and the UPC on the other grew steadily. The Ganda leaders particularly resented their inability to dominate a government composed mainly of members of other ethnic groups. Inside the UPC there were also divisions, because each member of parliament owed his election to local ethnic supporters rather than to his membership in a political party, and those supporters frequently put pressure upon their representatives to redress what they saw as an imbalance in the distribution of the material benefits of independence.

Faced with this dissatisfaction among some of his followers and with increasingly overt hostility in Buganda, Obote arrested five of his ministers and suspended the independence constitution in 1966. Outraged, the Ganda leaders ordered him to remove his government from the soil of the kingdom. Obote responded by sending troops under the leadership of Colonel Idi Amin to arrest the kabaka. The latter escaped to England, where he died in 1969, but the violence that accompanied the army's intervention fueled the anger of the Ganda still further. When Obote imposed a new republican constitution—appointing himself executive president, abolishing all the kingdoms, and dividing Buganda into administrative districts—he also lost the support of the peoples of southwestern Uganda. From this time internal friction grew in intensity, fostered by mutual suspicion between the rival groups, by assassination attempts against the president, and by the increasingly oppressive methods employed by the government to silence its critics.

At independence the export economy was flourishing without adversely affecting agricultural production for subsistence purposes, and the economy continued to improve, largely because of the demand and high prices paid for coffee. To meet accusations that the profits from exports did not benefit the producers to the extent that they should, Obote decided in 1969 to try to distribute the benefits arising from the prospering economy more widely. To this end he published a "common man's charter," aimed at removing the last vestiges of feudalism. The government, he said, would take a majority holding in the shares of the larger companies, mainly foreign-owned. In order to unite the country more firmly, he also produced a plan for a new electoral system in 1970 that would require successful candidates for parliament to secure votes in constituencies outside their home districts.

These proposals met with a cynical response in some quarters, and before they could be put into effect the government was overthrown. Obote had relied heavily upon the loyalty of Idi Amin, but the latter had been building support for himself within the army by recruiting from his own Kakwa ethnic group in the northwest. The army, theretofore composed of Acholi and their neighbours, Obote's own Lango people, now became sharply divided. Simultaneously, a rift developed between Obote and Amin, and in January 1971 the latter took advantage of the president's absence from the country to seize power.

Rise of Idi Amin

Tyranny under Amin. The coup was widely welcomed, notably by the Ganda, whose hatred for Obote made them well disposed toward any usurper. Several Western powers, including Britain, who feared the spread of communism, were also relieved at Obote's overthrow because they had become suspicious of what they saw as a tendency for his policies to move to the left.

Amin's inability to govern was soon revealed. Having had little education and virtually no officer training, he relied upon innate shrewdness and arbitrary violence to maintain himself in power. He destroyed the one potential centre of effective opposition by a wholesale slaughter of senior army officers loyal to Obote. To win more general support, he ordered all Asians who had not taken Ugandan nationality to leave the country in 1972. His move won considerable approval because many Africans believed that they had been exploited by the Asians, who controlled the middle and some of the higher levels of the country's economy. More perceptive critics recognized the difficulty of replacing Asian commercial expertise from internal resources, and their forebodings were quickly realized. Although a few wealthy Ugandans profited from their acquiescence and participation in Amin's actions, the majority of the commercial concerns formerly owned by Asians were given to senior army officers who rapidly squandered the proceeds and then allowed the businesses to collapse.

Most people in the countryside were able to ride out the total breakdown of the economy that took place in the middle and late 1970s because of the fertility of Uganda's soil. In the towns, an all-pervading black market developed, and dishonesty became the only means of survival. This economic and moral collapse stirred up criticism of the government, but any opposition was ruthlessly crushed by the army, and arbitrary violence, directed particularly against the better educated and therefore more critical members of the community, made the people afraid to rebel. This feeling of insecurity spread even to the leaders of Amin's army and weakened the president's hold on the country.

In an attempt to divert attention from Uganda's internal problems, Amin launched an attack on Tanzania in October 1978. It was the prelude to his downfall. Tanzanian troops, assisted by armed Ugandan exiles, quickly put Amin's demoralized army to flight. A coalition government of former exiles, calling itself the Uganda National Liberation Front (UNLF), with a former leading figure in the DP, Yusufu Lule, as president, took office on April 13, 1979. Disagreement over economic strategy and the fear that Lule was promoting the interests of his own Ganda people led to his being replaced in June by Godfrey Binaisa, but Binaisa's term of office was also short-lived. Supporters of Obote plotted his overthrow, and Obote returned to Uganda on May 27, 1980.

Instability after Amin

Obote's second presidency. In December 1980 Obote's party, the UPC, won a majority in highly controversial elections for parliament. The DP leadership reluctantly agreed to act as a constitutional opposition, but one man who had played a significant part in the military overthrow of Amin, Yoweri Museveni, refused to accept the UPC victory. Forming a guerrilla group in the bush near Kampala, he waged an increasingly effective campaign against the government.

With the support of the International Monetary Fund and other external donors, Obote tried hard to re-create the economy. Initially his efforts seemed to meet with some success, but two factors militated against him. First, the appalling inflation resulting from Amin's profligacy, and the black market to which it gave birth, made it impossible for urban wage earners to keep pace with rising prices. Salaried civil servants grew frustrated at the government's inability to increase their pay in line with their needs. Second, the guerrilla war drew strength from being based in Buganda, among people already suspicious of Obote. That strength grew as an ill-paid, ill-disciplined, and vengeful army, consisting largely of Acholi and Lango, ravaged the countryside for loot and took vengeance upon their longtime Ganda enemies.

Museveni in office. It was a split within the army itself—in particular, between its Acholi and Lango members—that led to Obote's overthrow and exile and to the seizure of power by an Acholi general, Tito Okello, but this could not prevent the victory of Museveni's force of southern fighters, now calling themselves the National Resistance Army (NRA). Museveni became president on Jan. 29, 1986, and the long period of rule by northerners came to an end. Pending the drafting of a new constitution, an indirectly elected National Resistance Council, dominated by the National Resistance Movement, acted as the national legislature.

Faced with the same problems that had confronted the UNLF in 1979 and Obote in 1980, problems exacerbated by the murderous struggle that had devastated one of the country's richest agricultural regions, Museveni announced a policy of moral as well as economic reconstruction. It was not easy to enforce. Sporadic military resistance to the new government continued, particularly in the north and east. Arms were plentiful, and dissatisfied persons were willing to use them to promote their ends. The NRA, despite the president's injunctions, sometimes proved as

Reconstruction

heavy-handed in dealing with opponents as Obote's forces had been. (K.In.)

Security did improve, however, and observers claimed that human rights were more widely protected. A constitution promulgated in 1995 led to the restoration of the local monarchies, and presidential elections were held in May 1996; Museveni easily won the majority of votes. In spite of continued economic growth, inflation and unemployment persisted, as did Uganda's dependence on fluctuating markets for its agricultural produce, and institutional corruption continued to be an issue in the 21st century. (Ed.)

THE COUNTRIES OF THE HORN OF AFRICA

Djibouti

The Republic of Djibouti (French: République de Djibouti; Arabic: Jumhūrīyah Jībūtī), a strategically located nation on the northeast coast of the Horn of Africa, is situated on the Strait of Mandeb, which lies to the east and separates the Red Sea from the Gulf of Aden. Small in size (8,950 square miles [23,200 square kilometres]), Djibouti is bordered by Eritrea to the north, Ethiopia to the west and southwest, and Somalia to the south. The Gulf of Tadjoura, which opens into the Gulf of Aden, bifurcates the eastern half of the country and supplies much of its 230 miles (370 kilometres) of coastline. The capital, Djibouti city, is built on coral reefs jutting into the southern entrance of the gulf; other major towns are Obock, Tadjoura, Ali Sabieh, and Dikhil.

The port of Djibouti

The nation's Lilliputian aspect belies its regional and geopolitical importance. The capital is the site of a modern deepwater port that serves Indian Ocean and Red Sea traffic and hosts a French naval base. Djibouti city is also the railhead for the only line serving Addis Ababa, the capital of Ethiopia.

PHYSICAL AND HUMAN GEOGRAPHY

The land. The landscape of Djibouti is varied and extreme, ranging from rugged mountains in the north to a series of low desert plains separated by parallel plateaus in the west and south. Its highest peak is Mount Mousa at 6,768 feet (2,063 metres); the lowest point, which is also the lowest in Africa, is the saline Lake Assal, 515 feet (157 metres) below sea level. Located at the convergence of the African and Arabian tectonic plates, the territory is geologically active. Slight tremors are frequent, and much of the terrain is littered with basalt from past volcanic activity.

Rainfall is rare, and vegetation is minimal. There are no regularly flowing surface watercourses in the republic. Cool-season (October to April) daily maximum temperatures at Djibouti city average 87° F (31° C); in the hot months 99° F (37° C) is the average daily maximum. Temperatures increase and humidity drops in midsummer as the arid khamsin wind blows off the inland desert.

The country's wildlife includes antelopes, gazelles, hyenas, jackals, and ostriches. Offshore, Djibouti's waters teem with many species of marine life, including tuna, barracuda, and grouper.

Djibouti is virtually a city-state, since about two-thirds of the population lives in or near the capital. Outlying towns are small trading centres that experience periodic population increases as camel caravans and sheep and goat herders encamp.

The people. *Ethnic composition.* Based on linguistic criteria, the two largest ethnic groups are the Somali and the Afar. Both groups adhere at least nominally to the Sunnite branch of Islām and speak related, but not mutually intelligible, eastern Cushitic languages.

The Afar (Denakil, or Danakil) speak a language that forms a dialect continuum with Saho. Saho-Afar is usually classified as an Eastern Cushitic language of the Afro-Asiatic language phylum. The Afar live in the sparsely populated areas to the west and north of the Gulf of Tadjoura. This region includes parts of several former as well as extant Afar sultanates. The sultans' roles are now largely ceremonial, and the social divisions within the traditional Afar hierarchy are of diminished importance.

The Somali, who also speak an Eastern Cushitic language, are concentrated in the capital and the southeastern quarter of the country. Their social identity is determined by clan-family membership. More than half of the Somali belong to the Issa, whose numbers exceed those of the Afar; the remaining Somali are predominately members of the Gadaboursi and Issaq clans.

Djibouti city is home to a long-established community of Yemeni Arabs and houses a sizable contingent of French technical advisers and military personnel. In recent decades these groups have been joined by small but significant numbers of ethnic Ethiopians as well as Greek and Italian expatriates.

Foreign residents

Language. The republic recognizes two official languages: French and Arabic. However, Somali is the most widely spoken language. The use of Afar is mostly restricted to Afar areas.

Demographic trends. Djibouti is the most urbanized country in sub-Saharan Africa, with some four-fifths of the population classified as urban. The annual rate of population increase is higher than the world average but has dropped significantly since the 1980s. More than half of the population is under the age of 20, and the average life expectancy is roughly 50 years.

Both the Afar and the Somali maintain ties with relatives living in neighbouring Eritrea, Ethiopia, and Somalia. Since independence, many newcomers from rural areas and regions beyond the national frontier have migrated to live with family members in Djibouti city. Drought and political conflicts in the Horn also have created large refugee movements into the republic.

The economy. Djibouti has few natural resources and extensive unemployment. Efforts to exploit geothermal energy are under way, but without substantial results. Salt was commercially exploited for export until the 1950s; today, surface deposits are collected and marketed through the informal sector of the economy. In rural areas, nomadic pastoralism is a way of life. Sheep and goats are

Men quarrying salt at Lake Assal, Djibouti.
Victor Englebert

raised for milk, meat, and skins, while camels are used for transport caravans. Agriculture is confined to a few wadis, which produce small yields of vegetables (mostly tomatoes) and dates. The fishing industry is still in the early stages of development. More than 90 percent of the country's food requirements is imported, mainly from France, Kenya, and Ethiopia.

Much of the country's economic potential lies in the transport and service sectors. An international airport is located at Ambouli. The port of Djibouti is a free-trade zone with modern container and refrigeration facilities and a rail link to Ethiopia. International telecommunications services are some of the best in sub-Saharan Africa. The capital has attracted several large commercial banks and provides a thriving entertainment industry necessary to a port city. There is also much unrecorded transshipment, via camels, dhows, and trucks, to bordering countries.

Major public works projects have been funded through foreign aid, and the government actively coordinates donors' efforts. In 1988 a paved road linking Tadjoura and the north with the capital was completed. The improvement of housing and the urban infrastructure continues.

Administration and social conditions. *Government.* Nine constitutional articles were adopted in February 1981. These provide for the election of a president by universal suffrage for a six-year term (renewable once), a 65-member National Assembly elected for a five-year term, and a Council of Ministers headed by the prime minister.

The ruling party

A single-party system, consisting of the Popular Assembly for Progress (Rassemblement Populaire pour le Progrès; RPP), was instituted by constitutional amendment in October 1981. Deputies to the National Assembly must be elected from a list supplied by the RPP; abstention from voting is the only legal form of opposition.

The judicial system recognizes several codes: French-based civil law, Islāmic law, and customary means of arbitration employed by the local populations.

The Djiboutian armed forces are supported by the presence of several thousand French troops, including a unit of the French Foreign Legion.

Djibouti belongs to the United Nations, the Organization of African Unity, the Arab League, and the nonaligned movement. In 1986 Djibouti city became the headquarters of the Inter-Governmental Authority on Drought and Development (IGADD), which comprises six eastern African nations.

Education. The educational system, although free, is burdened by the needs of Djibouti's young population. For many, formal education ends with early childhood training at local Qur'ān schools. Primary schools are run by the state and by Roman Catholic clergy; advancement to the secondary level in the public system is limited by the size of state facilities. A small vocational training program is offered, but no postsecondary educational institutions exist. Less than one-fifth of the adult population is literate.

Health. Many Djiboutians live in poor housing with inadequate water and sanitation. The infant mortality rate is high due to diarrhea and dehydration. Tuberculosis is a major health problem. Djibouti city has a hospital and several primary care clinics, and local dispensaries serve the rural areas.

Cultural life. Djibouti's only television and radio station, which broadcasts in French, Arabic, Afar, and Somali, is state-run, as is the weekly French-language newspaper, *La Nation*. The government sponsors several organizations dedicated to the preservation of traditional culture and dance.

In 1984 Djibouti entered the Olympics for the first time; since then its marathon runners have commanded international attention.

Major holidays are Independence Day, June 27, and the festivals of the Muslim calendar.

For statistical data on the land and people of Djibouti, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

On the eve of independence, Djibouti's viability as a sovereign state was questionable. However, fears that the Afar and the Issa Somali would become pawns in a struggle between the republic's rival neighbours, Ethiopia and Somalia, did not materialize. No Djiboutian political leader, either Afar or Somali, ever condoned unification with either of the larger states. Indeed, Djibouti established a peaceful international profile through a policy of strict neutrality in regional affairs. In keeping with friendship treaties with both Somalia and Ethiopia, the government refused to support armed groups opposing the neighbouring regimes, and it hosted negotiations between Somalia's and Ethiopia's leaders that resulted in a series of accords in 1988.

Balance between Afar and Somali

Djibouti's balanced posture in external relations was reflected in its internal politics. Hassan Gouled Aptidon, an Issa Somali, was elected to two consecutive terms as president in 1981 and 1987. Barkat Gourad Hamadou, an Afar serving as prime minister since 1978, was reappointed in 1987. Power appeared to be shared, with ministry appointments following a formula designed to maintain ethnic balance.

In the first years of self-government, though, ethnic tensions were evident. By 1978 the state had experienced two cabinet crises and changes of prime minister. Those ousted were Afars accused of fomenting ethnic strife. Since the banning of opposition parties in 1981, ethnic conflict in the political arena has been for the most part minimal. However, Issa predominance in the civil service, the armed forces, and the RPP was only slightly masked, and occasional tremors of social unrest disturbed Djibouti's superficial calm.

Challenges to Djibouti's stability could not be reduced to traditional Afar and Issa enmity; signs of the serious problems facing the young nation were also to be found in the urban demography of its capital. On the outskirts of the city an expansive squatter community known as Balbala, which originally developed just beyond the barbed-wire boundary erected by the French colonial administration to prevent migration to the capital, tripled in size within a decade after independence. In 1987 it was officially incorporated into the city, with the promise of development of basic water and sanitary services. Its growth continued owing to a high birth rate, rural migration, and displacement of persons from the urban core.

Conditions in the densely populated "native" quarters of Djibouti city were only marginally better than in Balbala. Structures were limited to wood and corrugated iron by colonial, and later national, restrictions on the construction and location of permanent dwellings. Distinct ethnic enclaves were identifiable: the retail centre surrounding the main mosque (Hamoudi Mosque) and the former caravan terminus (Harbi Square), housing the Arab community; the neighbourhoods radiating beyond this area, settled by the Issaq, Gadaboursi, and Issa Somali; and the quarter known as Arhiba, built by the French to house the Afar dockworkers recruited from the north of the colony in the 1960s.

As the urban infrastructure was developed, and as government-subsidized housing was realized through international aid programs, conditions in the old districts of the city improved. Yet the needs remained immense, and progress was accompanied by perceptions of ethnic favouritism. Discontent was also fostered by a high cost of living, unemployment, and a widening gap in living conditions between the majority of the population and the new urban elite.

Influx of refugees

Finally, government efforts to assist the people in desolate rural areas were complicated by the presence of large numbers of Ethiopian and Somalian refugees. Under the auspices of the United Nations High Commissioner for Refugees, thousands of persons who were displaced by the Ogaden dispute of the late 1970s and the droughts of the early 1980s were repatriated. However, continued civil upheavals in Somalia precipitated more refugee movement into the republic. Thus, the chronic conflicts of the troubled Horn of Africa encumbered the realization of Djibouti's national goals of unity, equality, and peace. (C.C.C.)

For later developments in the history of Djibouti, see the BRITANNICA BOOK OF THE YEAR.

Eritrea

Eritrea (Tigrinya: Ertra) is a small country of the Horn of Africa, located on the Red Sea. Its 600 miles (1,000 kilometres) of coastline extend from Cape Kasar, in the north, to the Strait of Mandeb, separating the Red Sea from the Gulf of Aden in the south. It is bounded on the northwest by The Sudan, on the south by Ethiopia, and on the southeast by Djibouti. Total land area (including islands off the coast) is 45,300 square miles (117,400 square kilometres). Eritrea's capital and largest city is Asmera.

Eritrea's coastal location has long been important in its history and culture—a fact reflected in its name, which is an Italianized version of Mare Erythraeum, Latin for "Red Sea." The Red Sea was the route along which Christianity and Islām reached the area and took firm hold among the people, and it was an important trade route that such powers as Turkey, Egypt, and Italy hoped to dominate by seizing control of ports on the Eritrean coast. Those ports promised access to the gold, coffee, and slaves sold by traders in the Ethiopian highlands to the south, and in the second half of the 20th century Ethiopia became the power from which the Eritrean people had to free themselves in order to create their own state. In 1993, after a war of independence that lasted nearly three decades, Eritrea became a sovereign country. During the long struggle, the people of Eritrea managed to forge a common national consciousness, but, with peace established, they now face the task of overcoming their ethnic and religious differences in order to raise the country from a poverty made worse by years of drought, neglect, and war.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Eritrea's land is highly variegated.

The central highlands

Running on a north-south axis through the middle of the country are the central highlands, a narrow strip of country some 6,500 feet (2,000 metres) above sea level that represents the northern reaches of the Ethiopian Plateau. Geologically, this plateau consists of a foundation of crystalline rock (*e.g.*, granite, gneiss, micaschist) that is overlain by sedimentary rock (limestone and sandstone) and then capped by basalt (rock of volcanic origin). The upper layers have been highly dissected by deep gorges and river channels, forming small steep-sided, flat-topped tablelands known as *ambas*. The highest point in the plateau is Mount Soira, at 9,885 feet (3,013 metres).

In the north of Eritrea the highlands narrow and then end in a system of hills, where erosion has cut down to the basement rock. To the east the plateau drops abruptly into a coastal plain. North of the Gulf of Zula, the plain is only 10 to 50 miles wide, but to the south it widens to include the Denakil Plain. This barren region contains a depression known as the Kobar Sink (more than 300 feet below sea level), the northern end of which extends into Eritrea. The coastal plain and the Denakil Plain are part of the East African Rift System and are sharply delimited on the west by the eastern escarpment of the plateau, which, although deeply eroded, presents a formidable obstacle to travelers from the coast.

The western flank of the central highlands is a broken and undulating plain that slopes gradually toward the border with The Sudan. It lies at an average elevation of 1,500 feet. The vegetation is mostly savanna, consisting of scattered trees, shrubs, and seasonal grasses.

Off the coast in the Red Sea is the Dahlak Archipelago, a group of more than 100 small coral and reef-fringed islands. Only a few of these islands have a permanent population.

Drainage. The Eritrean highlands are drained by four major rivers and numerous streams. Two of the rivers, the Gash and the Tekeze, flow westward into The Sudan. The Tekeze River (also known as the Satit) is a major tributary of the Atbara River, which eventually joins the Nile. The Gash River reaches the Atbara only during flood season. As it crosses the western lowlands, the Tekeze forms part of Eritrea's border with Ethiopia, while the upper course of the Gash, known as the Mereb River, forms the border on the plateau.

The other two major rivers that drain the highlands of Eritrea are the Barka and the Anseba. Both of these rivers flow northward into a marshy area on the eastern coast of The Sudan and do not reach the Red Sea. Several seasonal streams that flow eastward from the plateau reach the sea on the Eritrean coast.

Climate. Eritrea has a wide variety of climatic conditions, produced mainly by differences in altitude. The effects of elevation are seen most clearly in the wide range of temperatures experienced throughout the country. On the coast, Mitsiwa has one of the highest averages in the world (86° F, or 30° C), while Asmera, only 40 miles away yet more than 7,500 feet higher on the plateau, averages 62° F (17° C).

Mean annual rainfall on the plateau is 16 to 20 inches (400 to 500 millimetres), while on the western plain it is less than 16 inches. In both the highlands and the western lowlands, rainfall comes in summer, carried on a southwesterly airstream that decreases in amount of precipitation and length of rainy season as it proceeds toward the northeastern extremes of the plateau. The eastern edges of the plateau and, to a lesser extent, the coastal fringes receive much smaller quantities of rain from a northeasterly airstream that arrives in winter and spring. The interior regions of the Denakil Plain are practically rainless.

Settlement patterns. The environment is a determining factor in the distribution of Eritrea's population. Although

Mike Goldwater—Network/Matrix

Highland agriculturalists and lowland pastoralists

the plateau represents only one-quarter of the total land area, it is home to approximately one-half of the population, most of them sedentary agriculturalists. The lowlands on the east and west support a population mainly of pastoralists, although most of them also cultivate crops when and where weather conditions permit. As a rule, pastoralists follow various patterns of movement set by the seasons. Only the Rashaida, a small group in the northern hills, is truly nomadic.

Under Italian colonial rule from 1889 to 1941, Eritrea's urban sector flourished with the establishment of Asmera as the capital city, Aseb as a new port on the Red Sea, and a host of smaller towns on the plateau. In addition, Mitsiwa, an old and cosmopolitan port with strong links to Arabia, was expanded considerably. By the end of the colonial period, Eritrea had by far the highest urbanization rate in the Horn of Africa—approximately 15 percent—although a large part of the urban population was Italian nationals who eventually left the country. Subsequently, a population drift from the countryside to the towns was offset by emigration of Eritreans abroad, so that at the time of independence in 1993 the relative size of the urban sector remained unchanged.

The people. *Language groups.* Eritrea's population consists of several ethnic groups, each with its own language and cultural tradition. The Eritrean highlands are an extension of the Ethiopian Plateau to the south, and the bulk of the peasantry on the plateau belong to the Tigray, a group that also occupies the adjacent Ethiopian province of Tigray. The Tigrayan language, called Tigrinya, is spoken on both sides of the border and is the speech of nearly one-half of all Eritreans.

Inhabiting the northernmost part of the Eritrean plateau, as well as lowlands to the east and west, are people who speak the other major Eritrean language—Tigre. Tigre and Tigrinya are written in the same script and are descended from the same mother tongue (the ancient Semitic language of Ge'ez), but they are mutually unintelligible.

Also occupying the northern plateau are Bilin speakers, whose language belongs to the Cushitic family. The Rashaida are a group of Arabic-speaking nomads who traverse the northern hills.

On the southern part of the coastal region live Afar nomads, whose relatives live across the borders in Djibouti and Ethiopia; they are also called the Denakil, after the region that they inhabit. The coastal strip south of Mitsiwa, as well as the eastern flanks of the plateau, are occupied by Saho pastoralists. In the western plain, the dominant people are pastoralists of the Beja family, whose kin live across the border in The Sudan. Two small Nilotic groups, the Kunama and the Nara, also live in the west.

Religions. Historically, religion has been a prominent symbol of ethnic identity in the Horn of Africa. Christianity was established in the 4th century AD on the coast and appeared soon afterward in the plateau, where it was embraced by the Ethiopian highlanders. The Monophysite creed of the Ethiopian Orthodox church remains the faith of about half of the population of Eritrea, including nearly all the Tigray. Following the rise of Islām in Arabia, Muslim power flowed over the Red Sea coast, forcing the Ethiopians to retreat deep into their mountain fastness. Islām displaced other creeds in the lowlands of the Horn, and it remains the faith of nearly all the people inhabiting the eastern coast and the western plain of Eritrea, as well as the northernmost part of the plateau. Thus, while Islām claims nearly all pastoralists, Christianity is dominant among the peasant cultivators. (Muslims are significantly represented also in all towns of Eritrea, where they are prominent in trade.) In the perennial competition between cultivators and pastoralists over land, water, control of trade, and access to ports, religion has played an ideological role, and it remains a potent political force.

Christian highlanders and Muslim lowlanders

During the colonial period, Catholic and Protestant European missionaries introduced their own version of Christianity into Eritrea. They had considerable success among the small Kunama group, and they also attracted a few townspeople with the offer of modern education.

The economy. *Natural resources.* Salt mining, based on deposits in the Kobar Sink, is a traditional activity in Eritrea. Deposits of gold, copper, potash, and iron have been exploited at times in a minor way, and numerous other minerals have been identified, including zinc, feldspar, gypsum, asbestos, mica, and sulfur.

The area of cultivation is limited by climate and the uneven surface of the plateau, so that, of the 8 million acres (3.2 million hectares) of land considered cultivable, only 5 percent is being worked. There is room for expansion, however, especially if the country's considerable water resources are harnessed for irrigation.

In normal times, livestock is a valuable resource, and it has the potential to play a role in Eritrea's foreign trade. During the long war of independence, however, livestock was severely depleted. The fishing potential of the Red Sea is another underutilized resource.

Soil erosion, an age-old process, is particularly severe on the plateau. Encouraged by the steady expansion of cultivation, it has left few wooded areas and has created a shortage of fuel. The proximity of the oil-rich Arabian basin has occasionally raised expectations of discovering petroleum in Eritrea, but intermittent exploration since the days of Italian rule has failed to produce results.

Agriculture. Agriculture is by far the most important sector of the country's economy, providing a livelihood for about 80 percent of the population and normally accounting for the bulk of Eritrea's exports. Peasant cultivation and traditional pastoralism are the main forms of agricultural activity. These are not mutually exclusive occupations, since most peasants also keep animals and most pastoralists cultivate grains when possible. Both peasants and pastoralists produce primarily for their own subsistence, and only small surpluses are available for trade.

The staple grain products are an indigenous cereal named teff (*Eragostis abyssinica*) as well as corn (maize), wheat, barley, sorghum, and millet. Vegetables and fruit also are produced. Under Italian rule, modern irrigated plantations produced vegetables, fruit, cotton, sisal, bananas, tobacco, and coffee for the growing urban markets. This sector continued to operate under Ethiopian rule until it was disrupted by the long period of warfare.

Industry. A generation of war also damaged Eritrea's modest manufacturing sector, which also appeared during the Italian colonial period and provided many Eritrean workers with skills that enabled them later to find work abroad. Industry was based largely on the processing of agricultural products. Asmera was the main industrial centre, concerned with food products, beer, tobacco, textiles, and leather.

Red Sea ports

A petroleum refinery in the Red Sea port of Aseb, built by the Soviet Union for Ethiopia, is the prime industrial enterprise in Eritrea. Aseb also has a salt works, and there are a salt works and a cement works near the port of Mitsiwa.

Trade and transportation. Aseb and Mitsiwa have long been major ports of entry to Ethiopia, and that country, now landlocked, still has guarantees of access to the port facilities at Aseb. As a result, the bulk of Eritrea's trade is in the transit of goods to Ethiopia. A paved road links Aseb with Addis Ababa, and another paved road begins in Mitsiwa, climbs the plateau to Asmera, and continues south to the Ethiopian town of Adigrat. A railway was built by the Italians from Mitsiwa to Asmera, Keren, and Akordat, but it was rendered useless by the war of independence.

There are an international airport in Asmera and major airfields in Aseb and Mitsiwa.

Administration and social conditions. *Government.* After liberation from Ethiopia in May 1991, Eritrea was ruled by a provisional government that consisted essentially of the central committee of the Eritrean People's Liberation Front (EPLF). On May 19, 1993, shortly after a national referendum, this body proclaimed the Transitional Government of Eritrea, which was to rule for four years until the promulgation of a constitution and the election of a permanent government. The transitional government's legislative body, called the National Assembly, consisted of the original 30-member central committee of the EPLF augmented by 60 new members. At least 20 seats were to be reserved for women.

The National Assembly sets the policies of the government and elects the president. The president is assisted in implementing the government's policies by a State Council, containing cabinet ministers and the governors of Eritrea's provinces. In order to discourage ethnic rivalry, seats on the State Council are divided equally between Muslims and Christians, and political parties based on language or religion are banned.

Health and education. Chronic drought and decades of war have taken a toll on the health of Eritreans. The mortality rate at birth is 15 percent, and almost half of all infants die during their first year. The average life expectancy is about 50 years.

Only about 20 percent of Eritreans are literate, though the new government is intent on expanding education. Children are taught in their native languages, and in the higher grades they also are taught foreign languages, especially Arabic and English. There is a university in Asmera.

For statistical data on the land and people of Eritrea, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Precolonial Eritrea. *Rule from the highlands.* Beginning about 1000 BC, Semitic peoples from the South Arabian kingdom of Saba' (or Sheba) migrated across the Red Sea and absorbed the Cushitic inhabitants of the Eritrean coast and adjacent highlands. These Semitic invaders, possessing a well-developed culture, established the kingdom of Aksum, which, by the end of the 4th century AD, ruled the northern stretches of the Ethiopian Plateau and the eastern lowlands. An important trade route led from the port of Adulis, near modern Zula, to the city of Aksum, the capital, located in what is now the Ethiopian province of Tigray.

After extending its power at times as far afield as modern Egypt and Yemen, Aksum began to decline into obscurity in the 6th century AD. Beginning in the 12th century, however, the Ethiopian Zagwe and Solomonid dynasties held sway to a fluctuating extent over the entire plateau and the Red Sea coast. Eritrea's central highlands, known as the *mereb melash* ("land beyond the Mereb River"), were the northern frontier region of the Ethiopian kingdoms and were ruled by a governor titled *bahr negash* ("lord of the sea"). The control exercised by the crown over this region was never firm, and it became even more tenuous as the centre of Ethiopian power moved steadily southward to Gonder and Shewa. Highland Eritrea became a vassal fiefdom of the lords of Tigray, who were seldom on good terms with the dominant Amhara branch of the Ethiopian family.

The "land beyond the Mereb"

Contesting for the coastlands. Off the plateau, the pastoralist peoples in the west and north knew no foreign master until the early 19th century, when the Egyptians invaded the Sudan and raided deep into the Eritrean lowlands. The Red Sea coast, owing to its strategic and commercial importance, was contested by many powers. In the 16th century the Turks occupied the Dahlak Archipelago and then Mitsiwa, where they maintained, with occasional interruption, a garrison for more than three centuries. Also in the 16th century, Eritrea as well as Ethiopia were affected by the invasions of Aḥmad Grāñ, the Muslim leader of the sultanate of Adal. After the expulsion of Aḥmad's forces, the Turks temporarily occupied even more of Eritrea's coastal area. In 1865 the Egyptians obtained Mitsiwa from the Ottoman Porte. From there they pushed inland to the plateau, until in 1875 an Egyptian force that reached the Mereb River was annihilated by Ethiopian forces.

Meanwhile, the opening of the Suez Canal in 1869 had made the Red Sea a scene of rivalry among the world's most powerful states. Between 1869 and 1880 the Italian Rubattino Navigation company purchased from the local Afar sultan stretches of the Red Sea coast adjoining the village of Aseb. In 1882 these acquisitions were transferred to the Italian state, and in 1885 Italian troops landed at Mitsiwa, Aseb, and other locations. There was no resistance by the Egyptians at Mitsiwa, and protests made by the Turks and Ethiopians were ignored. Italian forces then systematically spread out from Mitsiwa toward the highlands. This expansion onto the plateau was initially opposed by Emperor Yohannes IV, the only Tigray to wear the Ethiopian crown in modern times, but Yohannes's successor, Menilek II, in return for weapons that he needed to fight possible rivals, acquiesced to Italian occupation of the region north of the Mereb. In the Treaty of Wichale, signed on May 2, 1889, Menilek recognized "Italian possessions in the Red Sea," and on Jan. 1, 1890, the Italian colony of Eritrea was officially proclaimed. From here, the Italians launched several incursions into Ethiopia, only to be decisively defeated by Menilek's army at the Battle of Adwa on March 1, 1896. Menilek did not pursue the defeated enemy across the Mereb. Soon afterward, he signed the Treaty of Addis Ababa, obtaining Italian recognition of Ethiopia's sovereignty in return for his recognition of Italian rule over Eritrea.

Colonial Eritrea. *Ruled by Italy.* In precolonial times there were no towns on the Eritrean plateau, urban centres being limited to the Red Sea coast. Under Italian rule, however, Eritrea's urban sector flourished. Tens of thousands of Italians arrived, bringing with them modern skills and a new lifestyle. Asmera grew into a charming city in Mediterranean style, the port of Mitsiwa was modernized and the port of Aseb improved, and a number of smaller towns appeared on the plateau. Road and rail construction linked the various regions of the colony, and a modest manufacturing sector also appeared, so that Eritreans acquired industrial skills.

Economic growth and modernization

At the same time, a sizable portion of Eritrea's best agricultural land was reserved for Italian farmers (although only a few actually settled on the land), and a small plantation sector was established to grow produce for the urban market. Eritrea's population grew rapidly during this period. Combined with the appropriation of land for Italian use, population growth created a shortage of land for the peasantry. This in turn stimulated a drift to the cities, which further expanded the urban population and produced an Eritrean working class.

Still, Eritrea had no valuable resources for exploitation and was not a wealth-producing colony for Italy. In fact, the colony was subsidized by the Italians, an extraneous factor that gave the local economy an artificial glow. Investment in education for Eritreans was negligible. There were very few schools for them, and even these were limited to the primary level. Also, Eritreans were not employed in the colonial service except as labourers and soldiers. As preparations for the invasion of Ethiopia got under way in the mid-1930s, several thousand Eritreans were recruited to serve in the invading army.

From Italian to Ethiopian rule. The invasion and occupation of Ethiopia beginning in 1935 marked the last chapter in Italian colonial history—a chapter that came to an end with the eviction of Italy from the Horn of Africa by the British in 1941. The following decade, during which Eritrea remained under British administration, was a period of intense political and diplomatic activity that shaped the future of Eritrea. Landlocked Ethiopia, coveting Eritrea's two seaports, launched an early campaign to annex the former colony, claiming that it had always been part of Ethiopia's domain. Lobbying of the Allied powers was carried out, and within Eritrea support for annexation was mobilized on the basis of religious loyalty by utilizing the services of Ethiopian Orthodox clergy. In order to promote the union of Eritrea with Ethiopia, a Unionist Party was formed in 1946; it was financed and guided from Addis Ababa.

Eritrea's Muslims had every good reason to oppose union with Ethiopia, where Christianity was the official religion and Muslims suffered discrimination in many areas of life. In order to counter Christian mobilization for union, a Muslim League was founded in 1947 to campaign for Eritrean independence. Thus, although there were some Christians who favoured independence and a few Muslims who were favourable to union with Ethiopia, the political division was drawn largely along sectarian lines.

Federation with Ethiopia. *Adoption of the federal scheme.* In 1950 the United Nations (UN), under the prompting of the United States, resolved to join Eritrea

to Ethiopia within two years in a federation that would provide the former colony with autonomy under its own constitution and elected government. Elections to a new Eritrean Assembly in 1952 gave the Unionist Party the largest number of seats—but not a majority, so it formed a government in coalition with a Muslim faction. The Eritrean constitution, prepared by the UN in consultation with Emperor Haile Selassie I of Ethiopia, was adopted by the Eritrean Assembly on July 10, 1952, and ratified by Haile Selassie on August 11. The act of federation was ratified by the emperor on September 11, and British authorities officially relinquished control on September 15.

Failure of the federal scheme. The federal scheme was short-lived, mainly because the government in Addis Ababa was unwilling to abide by its provisions. First, the Eritrean constitution sought to establish an equilibrium between ethnic and religious groups. It made Tigrinya and Arabic the official languages of Eritrea, and it allowed local communities to choose the language of education for their children. In the spirit of the constitution, the practice evolved of ensuring parity between Christians and Muslims in appointment to state office. This delicate balance was destroyed by Ethiopian interference, and Muslims were the initial losers, as Arabic was eliminated from state education and Muslims were squeezed out of public employment.

Suppression of Eritrean nationalism

Furthermore, the Ethiopians were anxious to eliminate any traces of separatism in Eritrea, and to that end they harrassed the leaders of the independence movement until many of them fled abroad. With the collaboration of their Unionist allies and in express violation of the constitution, they also suppressed all attempts to form autonomous Eritrean organizations. Political parties were banned in 1955, trade unions were banned in 1958, and in 1959 the name Eritrean Government was changed to "Eritrean Administration" and Ethiopian law was imposed. Eventually, even Ethiopia's Eritrean allies were alienated by crude intervention in the running of the Eritrean administration, financial disputes between Asmera and Addis Ababa, and mounting pressure on the Eritreans to renounce autonomy. The federation was already dead when, on Nov. 14, 1962, the Ethiopian parliament and Eritrean Assembly voted unanimously for the abolition of Eritrea's federal status, making Eritrea a simple province of the Ethiopian empire. Soon afterward, Tigrinya was banned in education; it was replaced by Amharic, the official language of Ethiopia.

The war of independence. *Beginning of armed revolt.* Muslims had been the first to suffer from Ethiopia's intervention in Eritrea, and it was they who formed the first opposition movement. In 1960, leaders of the defunct independence movement who were then living in exile announced the formation of the Eritrean Liberation Front (ELF). The founders, all Muslims, were led by Idris Mohammed Adam, a leading political figure in Eritrea in the 1940s. By the mid-1960s the ELF was able to field a small guerrilla force in the western plain of Eritrea, and thus began a war that was to last nearly three decades. In the early years, the ELF drew support from Muslim communities in the western and eastern lowlands as well as the northern hills. It also sought support from The Sudan, Syria, Iran, and other Islāmic states, and used Arabic as its official language. Ethiopian authorities portrayed the movement as an Arab tool and sought to rally Eritrean Christians to oppose it. Deteriorating economic and political conditions in Eritrea, however, combined to produce the opposite result.

During the 1930s and '40s the Eritrean economy had been stimulated by Italian colonial activity and by the special conditions created by World War II. After the war the local economy deflated, and it remained stagnant during the entire period of federation with Ethiopia. Many thousands of Eritreans were forced to emigrate to Ethiopia and the Middle East in search of employment. The suppression of the nascent trade-union movement further embittered this class, and many Eritrean workers—Muslims and Christians alike—rallied to the nationalist movement. In addition, the banning of Tigrinya in state education helped to turn an entire generation of Eritrean Christian students toward nationalism. Christians began to join the ELF in significant numbers at the end of the 1960s. Among them were students who had become politically radicalized in the Ethiopian student movement, which itself became a centre of opposition to the regime of Haile Selassie in the 1960s and '70s.

Highlanders join the rebellion

The spreading of revolution. The ELF was now able to extend its operations to the central highlands of Eritrea—the home of the Tigray. However, the arrival of the radical students coincided with the emergence of a serious rift between the leadership of the ELF, which was permanently resident in Cairo, and the rank and file, which remained in the field. The newcomers joined the opposition to the leadership, and in 1972 several groups that had defected from the ELF joined forces to form the Eritrean Liberation Front–People's Liberation Forces (ELF–PLF). For several years the two rival organizations fought each other as well as the Ethiopians. After a series of splits and mergers, the ELF–PLF came under the control of former students, among whom Christians predominated, and was renamed the Eritrean People's Liberation Front (EPLF), a Marxist and secular organization.

The EPLF had made its presence felt by 1974, when the imperial regime in Ethiopia collapsed. While a power struggle for the succession was waged in Addis Ababa, the two Eritrean fronts liberated most of Eritrea. By 1977 the nationalist revolution seemed on the verge of victory. It was not to be. A military dictatorship emerged in Addis Ababa—also espousing Marxism—and, armed and assisted by the Soviet bloc, the new Ethiopian regime was able to regain most of Eritrea in 1978. Warfare on a scale unprecedented in sub-Saharan Africa raged for the next decade. The Ethiopians made enormous efforts with massive land attacks and heavy weaponry, but they had no success against the small and lightly armed guerrilla forces.

The violence of war and indiscriminate oppression in their homeland turned most Eritreans against Ethiopia, thereby producing a steady stream of young recruits for the nationalist movement. Throughout the 1980s the fighting was carried out by the EPLF, which by 1981 had succeeded in eliminating the ELF and had emerged as the unchallenged champion of Eritrean nationalism. In the latter part of the decade, the Soviet Union terminated its military aid to Ethiopia. Unable to find another patron and faced with armed rebellion in other parts of the country, the regime in Addis Ababa began to falter. The final act occurred in 1991, when a rebel military offensive, led by the Tigray People's Liberation Front, swept toward the capital. The Ethiopian army disintegrated, and in May the EPLF assumed complete control of Eritrea.

Independence

Three decades of war had produced among Eritreans a sense of unity and solidarity that they had not known before. Indeed, an entire generation had come of age during the struggle for independence, which was now to become a reality. The new regime in Ethiopia supported Eritrea's independence, so that a separation was effected amicably. In a referendum held two years after liberation, on April 23–25, 1993, the overwhelming majority of Eritreans voted for independence. On May 21, Isaias Afwerki, the secretary-general of the EPLF, was made president of a transitional government, and on May 24 he proclaimed Eritrea officially independent. (G.C.L./Jo.Ms.)

Following independence, Eritrea enjoyed a thriving economy but, with the noteworthy exception of Ethiopia, maintained poor relations with neighbouring nations. Tension with The Sudan throughout the 1990s centred on mutual allegations that each had attempted to destabilize the other, and in late 1995 Eritrea engaged in a brief but violent conflict with Yemen over the Ḥanīsh Islands, a group of Red Sea islands claimed by both countries. Postindependence relations with Ethiopia, heretofore warm and supportive, deteriorated rapidly in 1998 and exploded into violence over the disputed hamlet of Badme. Following two years of bloodshed, a peace was negotiated in December 2000, but Eritrea's earlier economic and political progress had been shattered. Amid economic distress, loss of life, and a new flood of displaced persons, the first voices of discontent with government leadership were raised, and calls were made to promulgate the nation's constitution, which had been ratified in 1997. (Ed.)

For later developments in the history of Eritrea, see the BRITANNICA BOOK OF THE YEAR.

Ethiopia

Ethiopia (Amharic: Ityop'iya) is a landlocked country in the Horn of Africa. It shares frontiers with Eritrea to the north, Djibouti to the northeast, Somalia to the east, Kenya to the south, and The Sudan to the west and northwest. Its total area is 437,794 square miles (1,133,882 square kilometres). Lying completely within the tropical latitudes, the country is relatively compact, with similar north-south and east-west dimensions. The capital is Addis Ababa ("New Flower"), located almost at the centre of the country.

Ethiopia is one of the oldest countries in the world. Its territorial extent has varied over the millennia of its existence. In ancient times it remained centred around Aksum, an imperial capital located in the northern part of the modern state, about 100 miles (160 kilometres) from the Red Sea coast. The present territory was consolidated during the 19th and 20th centuries as European powers encroached into Ethiopia's historical domain. Ethiopia became prominent in modern world affairs first in 1896, when it defeated colonial Italy in the Battle of Adwa, and again in 1935–36, when it was invaded and occupied by fascist Italy. Liberation during World War II by the Allied powers set the stage for Ethiopia to play a more prominent role in world affairs. Ethiopia was among the first independent nations to sign the Charter of the United Nations, and it gave moral and material support to the decolonization of Africa and to the growth of Pan-African cooperation. These efforts culminated in the establishment of the Organization of African Unity and the United Nations Economic Commission for Africa, both of which have their headquarters in Addis Ababa.

Ethiopia's prominence in Africa and elsewhere faded during the 17-year (1974–91) rule of the Derg, a Marxist regime that brought the country to the verge of disaster with civil wars aggravated by famine and starvation. With yet another provisional government at the helm, its political future and economic prospects remain uncertain.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Geology.* Ethiopia's topography, one of the most rugged in Africa, is built on four geologic formations. Rocks of Precambrian origin (more than 540 million years in age) form the oldest basal complex of Ethiopia, as they do in most of Africa. The Precambrian layer is buried under more recent geologic formations—except in parts of northern, western, and southern Ethiopia, where there are exposed rock layers of granite and schist. Geologic processes of the Mesozoic Era (245 to 66.4 million years ago) contributed sedimentary layers of limestone and sandstone, most of which have been either eroded or covered by volcanic rocks. Younger sedimentary layers are found in northern Ethiopia and on the floors of the Rift Valley. Lava flows from the Tertiary and Quaternary periods (from 66.4 million years ago to the present) have formed basaltic layers that now cover two-thirds of Ethiopia's land surface with a thickness ranging from about 1,000 feet (300 metres) to almost 10,000 feet. The Rift Valley forms a spectacular graben (a massive tectonic trough) running right down the middle of the country from the northern frontier with Eritrea to the southern border with Kenya.

Relief. Although Ethiopia's complex relief defies easy classification, five topographic features are discernible. These are the Western Highlands, Western Lowlands, Eastern Highlands, Eastern Lowlands, and Rift Valley. The Western Highlands are the most extensive and rugged topographic component of Ethiopia. The most spectacular portion is the North Central massifs; these form the roof of Ethiopia, with elevations ranging from 15,157 feet (4,620 metres) for Mount Ras Dejen (or Dashen), the highest mountain in Ethiopia, to the Blue Nile and Tekeze river channels 10,000 feet below.

The Western Lowlands stretch north-south along the Sudanese border and include the lower valleys of the Blue Nile, Tekeze, and Baro rivers. With elevations of about 3,300 feet, these lowlands become too hot to attract dense settlement.

The Rift Valley is part of the larger East African Rift System. Hemmed in by the escarpments of the Western and Eastern Highlands, it has two distinct sections. The first part is in the northeast, where the valley floor widens into a funnel shape as it approaches the Red Sea and the Gulf of Aden. This is a relatively flat area interrupted only by occasional volcanic cones, some of which are active. The Denakil Plain, in which a depression known as the Kobar Sink drops as low as 380 feet below sea level, is found here. High temperatures and lack of moisture make the northeastern Rift Valley unattractive for settlement. The southwest section, on the other hand, is a narrow depression of much higher elevation. It contains Ethiopia's Lakes Region, an internal drainage basin of many small rivers that drain into Lakes Abaya, Abiyata, Awasa, Langano, Shala, Chamo, and Ziway. Together these lakes have more than 1,200 square miles (3,108 square kilometres) of water surface. The upper Rift Valley is one of the most productive and most settled parts of Ethiopia. The Rift Valley

The Eastern Highlands are much smaller in extent than the Western Highlands, but they offer equally impressive contrast in topography. The highest peaks are Mount Batu, at 14,127 feet, and Mount Chilalo, at 13,575 feet. The Eastern Lowlands resemble the long train of a bridal gown suddenly dipping from the narrow band of the Eastern Highlands and gently rolling for hundreds of miles to the Somalian border. Two important regions here are the Ogaden and the Hawd. The Shebele and Genale rivers cross the lowlands, moderating the desert ecology.

Drainage. Ethiopia has three principal drainage systems. The first and largest is the western system, which includes the watersheds of the Blue Nile (known as the Abay in Ethiopia), the Tekeze, and the Baro rivers. All three rivers flow west to the White Nile in The Sudan. The second system is the Rift Valley internal drainage system, composed of the Awash River, the Lakes Region, and the Omo River. The Awash flows northeast to the Denakil Plain before it dissipates into a series of swamps and Lake Abe at the border with Djibouti. The Lakes Region is a self-contained drainage basin, and the Omo flows south into Lake Rudolf, on the border with Kenya. The third system is that of the Shebele and Genale rivers. Both of these rivers originate in the Eastern Highlands and flow southeast toward Somalia and the Indian Ocean. Only the Genale (known as the Jubba in Somalia) makes it to the sea; the Shebele (in Somali, Shabeelle) disappears in sand just inside the coastline.

Soils. The soils of Ethiopia can be classified into five principal types. The first type is composed of eutric nitosols and andosols and is found on portions of the Western and Eastern Highlands. These soils are formed from volcanic material and, with proper management, have medium to high potential for rain-fed agriculture. The second group of soils, eutric cambisols and ferric and orthic luvisols, are found in the Simen plateau of the Western Highlands. They are highly weathered with a subsurface accumulation of clay and are characterized by low nutrient retention, surface crusting, and erosion hazards. With proper management, they are of medium agricultural potential. Fertile volcanic soils

The third group of soils is the dark clay soils found in the Western Lowlands and at the foothills of the Western Highlands. Composed of vertisols, they have medium to high potential for both food and agriculture but pose tillage problems because they harden when dry and become sticky when wet. Some of the rich coffee-growing regions of Ethiopia are found on these soils.

The fourth group is composed of yermosols, xerosols, and other saline soils that cover desert areas of the Eastern Lowlands and the Denakil Plain. Because of moisture deficiency and coarse texture, they lack potential for rain-fed agriculture. However, the wetter margins are excellent for livestock, and even the drier margins respond well to irrigation. The fifth soil group is lithosols found primarily in the Denakil Plain. Lack of moisture and shallow profile preclude cultivation of these soils.

Soil erosion is a serious problem in Ethiopia. Particularly in the northern provinces, which have been settled with sedentary agriculture for millennia, population density has caused major damage to the soil's physical base,

to its organic and chemical nutrients, and to the natural vegetation cover. Even on the cool plateaus, where good volcanic soils are found in abundance, crude means of cultivation have exposed the soils to heavy seasonal rain, causing extensive gully and sheet erosion.

Climate. Because Ethiopia is located in the tropical latitudes, its areas of lower elevation experience climatic conditions typical of tropical savanna or desert. However, relief plays a significant role in moderating temperature, so that higher elevations experience weather typical of temperate zones. Thus, average annual temperatures in the highlands are about 61° F (16° C), while the lowlands average about 82° F (28° C).

The three seasons

There are three seasons in Ethiopia. From September to February is the long dry season known as the *bega;* this is followed by a short rainy season, the *belg,* in March and April. May is a hot and dry month preceding the long rainy season (*kremt*) in June, July, and August. The coldest temperatures generally occur in December or January (*bega*) and the hottest in March, April, or May (*belg*). However, in many localities July has the coldest temperatures because of the moderating influence of rainfall.

Ethiopia can be divided into four rainfall regimes. Rain falls year-round in the southern portions of the Western Highlands, where annual precipitation may reach 80 inches (2,000 millimetres). Summer rainfall is received by the Eastern Highlands and by the northern portion of the Western Highlands; annual precipitation there may amount to 55 inches. The Eastern Lowlands get rain twice a year, in April–May and October–November, with two dry periods in between. Total annual precipitation varies between 20 and 40 inches. The driest of all regions is the Denakil Plain, which receives less than 20 inches and sometimes none at all.

Plant and animal life. Ethiopia's natural vegetation is influenced by four biomes. The first is savanna, which, in wetter portions of the Western Highlands, consists of montane tropical vegetation with dense, luxuriant forests and rich undergrowth. Drier sections of savanna found at lower elevations of the Western and Eastern Highlands contain tropical dry forests mixed with grassland. The second biome is mountain vegetation; comprising montane and temperate grasslands, this covers the higher altitudes of the Western and Eastern Highlands. The third biome, tropical thickets and wooded steppe, is found in the Rift Valley and Eastern Lowlands. The fourth biome is desert steppe vegetation, which covers portions of the Denakil Plain.

Ethiopia has had a rich variety of wildlife that in some cases has been reduced to a few endangered remnants. Lions, leopards, elephants, giraffes, rhinoceroses, and wild buffalo are rarities, especially in northern Ethiopia. The Rift Valley, the Omo River valley, and the Western Lowlands contain remnants of big-game varieties. Smaller game varieties such as foxes, jackals, wild dogs, and hyenas are found abundantly throughout the country.

Uniquely Ethiopian and among the most endangered species are the *walia* ibex of the Simen Mountains, the mountain nyala (a kind of antelope), the Simien jackal, and the gelada monkey. They are found in the Western and Eastern Highlands in numbers ranging from a few hundred for the *walia* ibex to a few thousand for the others. More abundant varieties found in the lowlands include such antelopes as the oryx, greater kudu, and waterbuck, various types of monkeys including the black-and-white colobus (known as *guereza* in Ethiopia and hunted for its beautiful long-haired pelt), and varieties of wild pig. In order to protect remaining species, the government has set aside 20 national parks, game reserves, and sanctuaries covering a total area of 21,320 square miles—about 5 percent of the total area of Ethiopia.

Settlement patterns. With only about 12 percent of the population urbanized, most Ethiopians live in scattered rural communities. In order to reduce traveling distance, homesteads are generally scattered to be near farm plots. Buildings vary between circular and rectangular styles and are constructed of materials readily found within the environment. Roofs are mostly thatched, although some well-to-do farmers opt for corrugated steel tops.

Modern urban centres in Ethiopia include the national capital of Addis Ababa and such regional centres as Dire Dawa (in the east), Jima (south), Nekemte (west), Dese (north-central), Gonder (northwest), and Mekele (north). Addis Ababa, founded by Menilek II in 1886, brought an end to the custom of "roving capitals" practiced by earlier monarchs. After World War II, "Addis" obtained the lion's share of investments in industry, social services, and infrastructure, so that it became the most attractive place for young people to seek opportunity.

The people. Ethiopians are ethnically diverse, but it is not helpful to attempt to distinguish among peoples by physical criteria alone. The most important differences are cultural, particularly in language and religion.

Languages. Ethiopia is a mosaic of about 100 languages that can be classified into four groups—Semitic, Cushitic, Omotic, and Nilotic. The Semitic languages are spoken primarily in the northern and central parts of the country; they include Ge'ez, Tigrinya, Amharic, Gurage, and Hareri. Ge'ez, the ancient language of the Aksumite empire, is used today only for religious writings and worship in the Ethiopian Orthodox church. Tigrinya is native to the northern province of Tigray. Amharic is the national language and is native to the central and northwestern provinces. Gurage and Hareri are spoken by relatively few people in the south and east.

The dominant Semitic languages

The most important Cushitic languages are Oromo, Somali, and Afar. Oromo, together with Amharic and Tigrinya, is one of the three most-spoken languages in Ethiopia; it is native to the western, southwestern, southern, and eastern areas of the country. Somali is dominant among inhabitants of the Ogaden and Hawd, while Afar is most common in the Denakil Plain.

The Omotic languages, chief among which is Walaita, are not widespread, being spoken mostly in the densely populated areas of the extreme southwest. The Nilotic language group is native to the Western Lowlands, with Kunama speakers being dominant.

Religion. Christianity was introduced to Ethiopia in the 4th century, and the Ethiopian Orthodox church (called Tewahdo in Ethiopia) is one of the oldest Christian sects in the world. The church has long enjoyed a dominant role in the culture and politics of Ethiopia, counting more than half of all Ethiopians (including most of the Amhara and Tigray) among its adherents and having served as the official religion of the ruling elite until the demise of the monarchy in 1974. It also has served as the repository of Ethiopia's literary tradition and its visual arts. The core area of Christianity is in the highlands of northern Ethiopia, but its influence is felt in the entire country.

Islām was introduced in the 7th century and is now practiced by more than one-quarter of Ethiopians. It is most important in the outlying regions, particularly in the Eastern Lowlands, but there are local concentrations throughout the country. Traditionally, the status of Islām has been far from equal with that of Christianity. However, the emperor Haile Selassie gave audiences to Muslim leaders and made overtures in response to their concerns, and under the Derg even more was done to give at least symbolic parity to the two faiths. Nevertheless, the perception of Ethiopia as "an island of Christianity in a sea of Islām" has continued to prevail among both highland Ethiopians and foreigners. There are now some concerns among highlanders that fundamentalist Muslim movements in the region and in neighbouring countries may galvanize sentiments for a greater role of Islām in Ethiopia.

About one-tenth of Ethiopians are animists who worship a variety of African deities. They are primarily located in the Western Lowlands and speak a variety of Nilotic languages, such as Kunama.

Judaism has long been practiced in the vicinity of the ancient city of Gonder. Most of the Ethiopian Jews—who call themselves Beta Israel but also have been known as Falasha—have relocated to Israel.

The economy. Under Emperor Haile Selassie (reigned 1930–74), Ethiopia's economy enjoyed a modicum of free enterprise. The production and export of cash crops such as coffee were advanced, and import-substituting manu-

factures such as textiles and footwear were established. Especially after World War II, tourism, banking, insurance, and transport began to contribute more to the national economy. The Derg regime, which ruled from 1974 to 1991, nationalized all means of production, including land, housing, farms, and industry. Faced with uncertainties on their land rights, the smallholding subsistence farmers who form the backbone of Ethiopian agriculture became reluctant to risk producing surplus foods for market. Food shortages, already made serious by drought and civil war, worsened, and famine continued until the Derg finally collapsed. Under the present regime, which is essentially extracted from a rebel faction, land is still state-owned and is tenurable only by leasing from the government. In addition, an uncertain political climate has precluded significant internal or external investment in the country's economy. Ethiopia therefore remains among the poorest countries in the world.

Resources. Ethiopia's most promising resource is its agricultural land. Although soil erosion, overgrazing, and deforestation have seriously damaged the plateaus, nearly half the potentially cultivable land is still available for future use. Most of the reserve land is located in parts of the country that have favourable climatic conditions for intensive agriculture. In addition, Ethiopia is the richest country in Africa in number of livestock, including cattle. With better management of grazing lands and breeding, livestock raising has the potential to meet the demands of internal as well as export markets.

Ethiopia has many large rivers, but, with the exception of the Awash, they have yet to be exploited fully for hydroelectric power and irrigation. The role of minerals in Ethiopia's economy is also small. Only gold and platinum are of significance. However, there are potentials for copper, potash, lead, manganese, aluminum, chromium, cobalt, sulfur, and many others.

Agriculture. Agriculture contributes almost half of Ethiopia's gross domestic product (GDP). There are three types of agricultural activity. The first (and by far the most important) is the subsistence smallholder sector, which produces most of the staple grains such as teff, wheat, barley, and oats (on the cooler plateaus) and sorghum, corn (maize), and millet (in warmer areas) and pulses such as chickpeas, peas, beans, and lentils. Farm plots are very small, ranging from 3 to 6 acres (1.2 to 2.5 hectares).

The second type of agriculture is cash-cropping. Products include coffee, oilseeds, beeswax, qat (a stimulant leaf), and sugarcane. Coffee, which is native to Ethiopia, is the single most important export.

Subsistence livestock raising, the third agricultural activity, is important in the peripheral lowlands of Ethiopia. Large herds may be kept by a family as it migrates each season in search of grazing and water.

Fishing. Fish is not a major item in the diet of highland Ethiopians (except during Lent for Christians). Favourite species are harvested from freshwater lakes and rivers in the highlands and the Rift Valley. Most of the fish sold locally is produced by small operators whose scale of operation and technology is inadequate for export production.

Mining and quarrying. Compared to its potential, this sector contributes very little to the country's economy (less than 1 percent of its GDP). Gold is mined at Kibre Mengist in the south and platinum at Yubdo in the west. Also important are rock salt from the Denakil Plain and quarried building materials such as marble.

Modern manufacturing and cottage industry

Industry. Modern manufacturing contributes only about 7 percent to the GDP of Ethiopia. Products are primarily for domestic consumption. Among the most important are processed foods and beverages, textiles, tobacco, leather and footwear, and chemical products. Cottage industry and small enterprises are more important than industrial manufacturing in offering nonfarm employment and in producing a variety of consumer goods—for example, furniture, farming and construction implements, utensils, woven fabric, rugs, leathercrafts, footwear, jewelry, pottery, and baskets. Some of these products reach the tourist market. The size of the cottage industry is not known exactly, but government estimates put it at 4 percent of GDP.

Energy. Energy is derived primarily from firewood and charcoal. Ethiopia's long dependence on these sources has contributed to the depletion of its trees and to the erosion of its soil. Hydroelectricity, the most important source of power for industries and major cities, is generated at three stations on the Awash, two on the Blue Nile or its tributaries, and one on the Shebele. However, these represent only a small fraction of Ethiopia's potential.

A refinery at the Eritrean port of Aseb supplies Ethiopian motor vehicles and trains with gasoline and diesel fuel. Ethiopia itself does not extract petroleum.

Finance. Before the Derg's nationalization of banks and insurance companies, financial institutions were among the best-run and best-managed establishments in Ethiopia. The National Bank of Ethiopia is the country's central bank and is also responsible for regulatory functions. The Commercial Bank of Ethiopia is the largest commercial bank, with branches throughout the country. The Agricultural and Industrial Development Bank provides

loans primarily for agricultural and livestock development; it also directs small amounts toward investment in manufacturing.

Trade. Ethiopia's exports are almost entirely agricultural. Coffee alone is responsible for more than 50 percent of foreign-exchange earnings; other exported products are hides and skins, oilseeds, and vegetables. Major export destinations are the United States, western Europe, Japan, and Saudi Arabia. Manufactures, especially machinery and transport equipment, account for almost three-quarters of the value of imports; food products and fuels are also important. With more being spent on imports than is earned from exports, Ethiopia's balance of payments has been negative for many years.

Transport. Among the more successful developments in Ethiopia has been the road system. During the brief Italian occupation of 1935–41, highways were opened up linking Addis Ababa to the provinces, and after World War II the Imperial Highway Authority opened new feeder roads to isolated localities. Road construction and maintenance slowed during the decade of civil war in the 1980s. With the secession of Eritrea, Ethiopia no longer has direct access to the Red Sea ports of Aseb and Mitsiwa. This loss has placed greater importance on the railway between Addis Ababa and Djibouti, which was originally built by a French company between 1897 and 1917.

The air transport system

Ethiopia's air transport system has enjoyed a success unparalleled in Africa. The internal network of Ethiopian Airlines (a state-owned but independently operated carrier) is well developed, connecting major provincial capitals and locations of tourist interest. Its international network provides excellent service to Africa, Europe, and Asia. Bole International Airport, near Addis Ababa, serves other African and European airlines and is also an acknowledged centre for pilot training and aircraft maintenance.

Tourism. Although tourism was curtailed during the period of Derg rule, Ethiopia can once again realize the tourist potential of such historical wonders as the rock-hewn churches of Lalibela, the antiquities at Aksum, and the Gonder castles. Of equal attraction are Ethiopia's diverse peoples, their intriguing cultures, and the natural beauty of their land.

Administration and social conditions. *Government.* Ethiopia's ancient system of feudal government experienced significant changes under Haile Selassie I, who carefully grafted onto the traditional governing institutions a weak parliament of appointed and elected legislators, a judiciary with modernized civil and criminal codes and a hierarchy of courts, and an executive cabinet of ministers headed by a prime minister but answerable to himself. The Derg took power in 1974 and promised to bring revolutionary change to Ethiopia. Promulgating itself as the Provisional Military Administrative Council (PMAC) and later as the Workers' Party of Ethiopia (WPE), the Derg instituted a Soviet-style government with a state president and a house of deputies that were answerable to a revolutionary council with a politburo at the top. In May 1991 the Ethiopian People's Revolutionary Democratic Front (EPRDF) entered the capital. The EPRDF introduced a temporary constitution called the National Charter, created an 87-member assembly known as the State Council, and proceeded to form a cabinet for the Transitional Government of Ethiopia (TGE). The TGE endorsed the secession of Eritrea, realigned provincial boundaries in an attempt to create ethnic homogenates, demobilized the national armed forces, and suspended the courts and enforcing agencies.

Education. Ethiopia maintains two educational systems. The traditional system is rooted in Christianity and Islām. Christian education at the primary level is often conducted by clergy in the vicinity of places of worship. Higher education, with emphasis on traditional Christian dogma, is still run by most major centres of worship, the most prominent being monasteries in the northern and northwestern provinces. Graduation from these centres leads to a position within the priesthood and church hierarchy.

Modern education

Modern education was an innovation of the emperors Menilek II (reigned 1889–1913) and Haile Selassie I (1930–74), who established an excellent, but limited, system of primary and secondary education. In addition, colleges of liberal arts, technology, public health, building, law, social work, business, agriculture, and theology were opened in the 1950s and '60s. In 1961 Haile Selassie I University (now Addis Ababa University) was created to centralize the administration of higher education in the country. The Derg expanded primary education and gave university designation to the Agricultural College in Alemaya near Harer and to the Medical College in Gonder. Nevertheless, with only about 40 percent of the primary, 15 percent of the secondary, and 1 percent of the tertiary age groups enrolled, Ethiopia's educational system is still grossly inadequate.

Health and welfare. Ethiopia's health-care system includes primary health centres, clinics, and hospitals. Only major cities have hospitals with full-time physicians, and most of the hospitals are in Addis Ababa. With some 30,000 people per physician, access to modern health care is very limited. Fewer than 60 percent of births are attended by health staff, and infant mortality is approximately 130 per 1,000 live births. Life expectancy at birth is 47 years.

Most health facilities are government-owned. Hopes of increasing the number of Ethiopian doctors suffered during the Derg era, when many either left the country or failed to return from specialized training abroad. Two medical schools continue to produce general practitioners and a few specialists, but the scale of output does not match the rising demand. Under the Derg, health facilities deteriorated from lack of maintenance and from shortages of equipment and drugs. Widespread use of traditional healing continues to be important, including such specialized occupations as bonesetting, midwifery, and minor surgery (including circumcision).

Cultural life. The cultural heritage of Ethiopians resides in their religions, languages, and extended families. All major language and religious groups have their own cultural practices (which also vary by geographic location); however, there are commonalities that form strong and recognizable national traits. Most Ethiopians place less importance on artifacts of culture than they do on an idealized ethos of cultural refinement as reflected in a respect for human sanctity, the practice of social graces, and the blessings of accumulated wisdom. Religion provides the basic tenets of morality. The invocation of God is often all that is needed to seal agreements, deliver on promises, and seek justifiable redress. Hospitality is reckoned the ultimate expression of grace in social relations. Old age earns respect and prominence in society, especially because of the piety, wisdom, knowledge, prudence, and altruism that it is supposed to bestow.

Major holidays

The influence of the Ethiopian Orthodox church on the national culture has been strong. Easter (Amharic: Yetinsa-e Be-al, or Fassika), Christmas (Yelidet Be-al, or Genna), and the Finding of the True Cross (Meskel) have become dominant national holidays. In an effort to reduce the dominance of the Christian church, both the Derg and the current regime have elevated the status of Islām. Major Islāmic holidays include ʿĪd al-Fiṭr (ending the fast of Ramaḍān) and ʿĪd al-Aḍḥā (ending the period of pilgrimage to Mecca). (A.Me.)

For statistical data on the land and people of Ethiopia, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

From prehistory to the Aksumite kingdom. That life is of great antiquity in Ethiopia is indicated by the Hadar remains, a group of skeletal fragments found in the lower Awash River valley. The bone fragments belong to *Australopithecus afarensis,* an apelike creature that lived about four million years ago and may have been an ancestor of modern humans.

Sometime between the 8th and 6th millennia BC, pastoralism and then agriculture developed in northern Africa and southwestern Asia, and, as the population grew, an ancient tongue spoken in this region fissured into the modern languages of the Afro-Asiatic, or Hamito-Semitic,

family. This family includes the Cushitic and Semitic languages now spoken in Ethiopia. During the 2nd millennium BC, cereal grains and the use of the plow were introduced into Ethiopia from the region of the Sudan, and a people speaking Ge'ez (a Semitic language) came to dominate the rich northern highlands of Tigray. There, in the 7th century BC, they established the kingdom of Da'amat. This kingdom dominated lands to the west, obtaining ivory, tortoiseshell, rhinoceros horn, gold, silver, and slaves and trading them to South Arabian merchants.

After 300 BC, Da'amat deteriorated as trade routes were diverted eastward for easier access to coastal ports. Subsequent wars of aggrandizement led to unification under the inland state of Aksum, which, from its base on the Tigray Plateau, controlled the ivory trade into the Sudan, other trade routes leading farther inland to the south, and the port of Adulis on the Gulf of Zula. Aksum's culture comprised Ge'ez, written in a modified South Arabian alphabet, sculpture and architecture based on South Arabian prototypes, and an amalgam of local and Middle Eastern dieties. Thus, evidence exists of a close cultural exchange between Aksum and the Arabian peninsula, but there are no scholarly grounds for the common belief that South Arabian immigrants actually peopled and created Aksum, even if many of them visited or even came to live there. Nevertheless, the ancient cultural exchange across the Red Sea became enshrined in Ethiopian legend in the persons of Makeda—the Queen of Sheba—and the Israelite king Solomon. Their mythical union was said to have produced Menilek I, the progenitor of Ethiopia's royal dynasty.

Contact with Arabia

By the 5th century Aksum was the dominant trading power in the Red Sea. Commerce rested on sound financial methods, attested to by the minting of coins bearing the effigies of Aksumite emperors. In the anonymous Greek travel book *Periplus Maris Erythraei*, written in the 1st century AD, Adulis is described as an "open harbour" containing a settlement of Greco-Roman merchants. It was through such communities, established for the purposes of trade, that the Monophysite Christianity of the eastern Mediterranean reached Ethiopia during the reign of Emperor Ezanas (*c.* 303–*c.* 350). By the mid-5th century, monks were evangelizing among the Cushitic-speaking Agew people to the east and south.

At its height, Aksum extended its influence northward to the southernmost reaches of Egypt, westward to the Cushite kingdom of Meroe, southward to the Omo River, and eastward to the spice coasts on the Gulf of Aden. Even the South Arabian kingdom of the Himyarites, across the Red Sea in what is now Yemen, came under the suzerainty of Aksum. In the early 6th century, Emperor Caleb (Ella-Asbeha; reigned *c.* 500–534) was strong enough to reach across the Red Sea in order to protect his coreligionists in Yemen against persecution by a Jewish prince. However, Christian power in South Arabia ended after 572, when the Persians invaded and disrupted trade. They were followed 30 years later by the Arabs, whose rise in the 7th and 8th centuries cut off Aksum's trade with the Mediterranean world.

The Zagwe and Solomonid dynasties. As Christian shipping disappeared from the Red Sea, Aksum's towns lost their vitality. The Aksumite state turned southward, conquering adjacent, grain-rich highlands. Monastic establishments moved even farther to the south—for example, a great monastery was founded near Lake Hayk in the 9th century. Over time, one of the subject peoples, the Agew, learned Ge'ez, became Christian, and assimilated their Aksumite oppressors to the point that Agew princes were able to transfer the seat of the empire southward to their own region of Lasta. Thus the Zagwe dynasty appeared in Ethiopia. Later ecclesiastical texts accused this dynasty of not having been of pure "Solomonid" stock (*i.e.*, not descended from the union of Solomon and the Queen of Sheba), but it was in the religious plane that the Zagwe nonetheless distinguished themselves. At the Zagwe capital of Roha, Emperor Lalibela (reigned *c.* 1185–1225) directed the hewing of 11 churches out of living rock—a stupendous monument to Christianity, which he and the other Zagwes fostered along with the Ethiopianization of the countryside.

The rock churches of Lalibela

The church hierarchy, however, continued to view the Zagwes with distaste, favouring instead the Amhara princes of northern Shewa, who claimed legitimacy as the avatars of the Aksumite dynasty. When Shewa's king Yekuno Amlak rebelled in 1270, he was supported by an influential faction of monastic churchmen, who condoned his regicide of Emperor Yitbarek and legitimated his descent from Solomon. The genealogy of the new Solomonid dynasty was published in the early 14th century in the *Kebra Negast* ("Glory of the Kings"), a pastiche of legends that related the birth of Menilek I, associated Ethiopia with the Judeo-Christian tradition, and provided a basis for Ethiopian national unity through the Solomonid dynasty, Shewan culture, and the Amharic language. Well-armed ideologically, the Ethiopian state was prepared for a struggle impending in its eastern and southern provinces, where Christianity was being pushed back by the forces of Islām.

Islāmic missionary preaching had led to the conversion of many pagan people living on the peripheries of Ethiopian rule. In the late 13th century, various Muslim sultanates on Ethiopia's southern border fell under the hegemony of Ifat, located on the eastern Shewan Plateau and in the Awash valley. Early in his reign (1314–44), the Ethiopian emperor Amda Tseyon marched southward, where he established strategic garrisons and divided jurisdictions into *gults*, or fiefs, whose holders paid an annual tribute. His heavy taxation of exports, especially of gold, ivory, and slaves that were transshipped from Ifat to Arabia, resulted in several rebellions led by Muslim sultans. Amda Tseyon and his successors replied with brutal pacification campaigns that carried Solomonid power into the Awash valley and even as far as Seylac (Zeila) on the Gulf of Aden.

Aggrandizement into non-Christian areas eventually stimulated an internal reform and consolidation of the Christian state. As heads of the church, Solomonid monarchs actively participated in the development of religious culture and discipline by building and beautifying churches, repressing pagan practices, and promoting the composition of theological and doctrinal works. Such close connection between church and state inevitably brought conflict. Because of the role played by the monasteries in the accession of the Solomonid dynasty, many of them had been given perpetual title to considerable landed benefices. Such power allowed the monasteries at times to intervene in disputes over succession to the Solomonid throne and even openly to fight the reigning monarch. On the other hand, the monk Abba Ewostatewos (*c.* 1273–1352) preached isolation from corrupting state influences and a return to Biblical teachings—including observance of the Judaic Sabbath on Saturday in addition to the Sunday observance, an idea deeply held by the rural masses. The great emperor Zara Yakob (reigned 1434–68) conceded the latter point in 1450 at the Council of Mitmak, but he also initiated severe reforms in the church, eliminating abuses by strong measures and executing the leaders of heretical sects. Zara Yakob also conducted an unsuccessful military campaign to annihilate the Beta Israel, or Falasha, a group of Agew-speaking Jews who practiced a non-Talmudic form of Judaism.

Zara Yakob valued national unity above all and feared Muslim encirclement. In 1445 he dealt Ifat such a crushing military defeat that hegemony over the Muslim states passed to the sultans of Adal, in the vicinity of Harer. About 1520 the leadership of Adal was assumed by Aḥmad ibn Ibrāhīm al-Ghāzī, a Muslim reformer who became known as Sahib al-Fath ("the Conqueror") to the Muslims and Aḥmad Grāñ ("Ahmad the Left-Handed") to the Christians. Aḥmad drilled his men in modern Ottomon tactics and led them on a jihad, or holy war, against Ethiopia, quickly taking areas on the periphery of Solomonid rule. In 1528 Emperor Lebna Denegel was defeated at the battle of Shimbra Kure, and the Muslims pushed northward into the central highlands, destroying settlements, churches, and monasteries. In 1541 the Portuguese, whose interests in the Red Sea were imperiled by Muslim power, sent 400 musketeers to train the Ethiopian army in European tactics. Emperor Galawdewos (reigned 1540–59) opted for a hit-and-run strategy and on Feb. 21, 1543, caught Aḥmad in the open near Lake Tana and

The invasions of Aḥmad Grāñ

killed him in action. The Muslim army broke, leaving the field and north-central Ethiopia to the Christians.

The Age of the Princes. Meanwhile, population pressures had mounted among the Oromo, a pastoral people who inhabited the upper basin of the Genalē (Jubba) River in what is now southern Ethiopia and northern Kenya. Oromo society was based upon an "age-set" system known as *gada*, in which all males born into an eight-year generation moved together through all the stages of life. The warrior classes (*luba*) raided and rustled in order to prove themselves, and in the 16th century they began to undertake long-distance expeditions into the recently depopulated Ethiopian Plateau, stopping only when blocked by physical obstacles or by military might. By 1600 the Oromo had spread so widely in Ethiopia that Emperor Sarsa Dengel (reigned 1563–97) limited his government to what are now Eritrea, the northern regions of Tigray and Gonder, and parts of Gojam, Shewa, and Welo. These constituted an easily defensible, socially cohesive unit that included mostly Christian, Semitic-speaking agriculturalists. The church continued to rail against the Oromo threat and exhorted its flock to restore Ethiopia to its ancient domains, but the Monophysite faith soon found itself facing a different kind of threat from Roman Catholicism.

Following close upon the Portuguese musketeers were missionaries who, sent by the Jesuit founder St. Ignatius of Loyola, sought to convert Ethiopia to the Western church. The most successful of these was the Jesuit Pedro Páez; his personal authority and eminent qualities were such that Emperor Susenyos (reigned 1607–32) was persuaded to accept the doctrine of the dual nature of Christ and to notify the pope of his acceptance. This apostasy attracted the elites but repulsed the masses and the monks, and Susenyos was forced to abdicate in favour of his son Fasilides (reigned 1632–67).

The Gonder period

Fasilides established a new capital at Gonder, a trading centre north of Lake Tana that connected the interior to the coast. At its height about 1700, the city supported the arts and educational, religious, and social institutions as well as Beta Israel craftspeople, Muslim traders, and a large Oromo population of farmers, day labourers, and soldiers. In order to protect Orthodox Christendom from the pagan Oromo, who were moving into southern Tigray and southeastern Gonder province, the monarchy turned to a newly assimilated Oromo aristocracy. Eventually the emperors at Gonder became little more than local magnates protected by Oromo generals. Meanwhile, agricultural development in the Gībē River basin was leading to the formation of Oromo states just south of Shewa, the Gonga people were developing their own states in the Kefa highlands on the west bank of the Omo River, and a line that claimed Solomonid descent was returning northern Shewa to Amhara rule. By the reign of Emperor Tekle Haimanot I (1706–08), little was left of the central government. The Zamana Masafent ("Age of the Princes"), 150 years of feudal anarchy, had commenced.

For most Ethiopians, life during the Age of the Princes was difficult. Everyone had a niche in society, few moved from class to class, and practically nobody questioned the social order. As armies traversed the highlands, ruining the countryside and forcing farmers off the land and onto the field of battle, the self-sufficient rural economy of the north broke down. The balance of power shifted southward to untouched Shewa, which prospered in the growing trade of the Gībē states. Shewa's self-proclaimed king, Sahle Selassie (reigned 1813–47), and his successors expanded southward, so that by 1840 they controlled most of Shewa to the Awash River and enjoyed suzerainty as far south as Guragē.

To the north, Kassa Hailu was ending the Age of the Princes. After serving as a mercenary in Gojam, Kassa returned to his native Kwara in the western lowlands, where he prospered as a highwayman and built a good, small army. By 1847 he monopolized the lowlands' revenues from trade and smuggling, forcing Gonder's leading magnates to integrate him into the establishment. Finally, in April 1853 at Takusa, Kassa defeated Ras (Prince) Ali, the last of the Oromo lords. After consolidating his rule over Tigray to the north, Kassa was crowned Emperor Tewodros II on Feb. 9, 1855. Later that year he marched south and forced the submission of Shewa.

Tewodros II, Yohannes IV, and Menilek II. Although Tewodros' first years were marked by attempts at social justice, his effort to establish garrisons nationwide lost the allegiance of the already heavily taxed peasantry, and he alienated parish clergy by nationalizing "excess" church land. Such political ineptitude gave heart to the regional aristocrats, who returned to conspiracy. The emperor held Ethiopia together only through coercion, and in 1861, finally understanding his conundrum, he conceived a bold foreign policy to regain popular support. In 1862 Tewodros offered Britain's Queen Victoria an alliance to destroy Islām. The British ignored the scheme, and, when no response came, Tewodros imprisoned the British envoy and other Europeans. This incident led to an Anglo-Indian military expedition in 1868. Sir Robert Napier, the commander, paid money and weapons to Kassa, a *dejazmatch* (earl) of Tigray, in order to secure passage inland, and on April 10, on the plains below Āmba Maryam (or Mek'dela), British troops defeated a small imperial force. In order to avoid capture, Tewodros committed suicide.

The Tigrayan Kassa took the imperial crown as Yohannes IV on Jan. 21, 1872. After ejecting two Egyptian armies from the highlands of Eritrea in 1875–76, Yohannes moved south, forcing Shewa's king Menilek to submit and to renounce imperial ambitions. Yohannes thus became the first Ethiopian emperor in 300 years to wield authority from Tigray south to Guragē. He then sought to oust the Egyptians from coastal Eritrea, where they remained after the Mahdists had largely taken over the Sudan, but he was unable to prevent Italy from disembarking troops at Mitsiwa (now Massawa) in February 1885. In order to weaken the emperor, Rome tried to buy Menilek's cooperation with thousands of rifles; the Shewan king remained faithful to Yohannes but took the opportunity in January 1887 to incorporate Harer into his kingdom. Meanwhile, Yohannes repulsed Italian forays inland, and in 1889 he marched into the Sudan to avenge Mahdist attacks on Gonder. On March 9, 1889, with victory in his grasp, he was shot and killed at Metema.

The Treaty of Wichale

Menilek declared himself emperor of Ethiopia on March 25, and at Wichale (or Ucciali, as the Italians called it) in Tigray on May 2 he signed a treaty of amity and commerce granting Italy rule over Eritrea. The Italian version of Article XVII of the Treaty of Wichale made Rome the medium for Ethiopia's foreign relations, whereas the Amharic text was noncommital. Learning that Rome had used the mistranslation to claim a protectorate over all of Ethiopia, Menilek first sought a diplomatic solution; meanwhile, during 1891–93, he sent expeditions south and east to obtain gold, ivory, musk, coffee, hides, and slaves to trade for modern weapons and munitions. In December 1895, after two years of good harvests had filled Ethiopia's granaries, Menilek moved his army into Tigray.

Rome believed that as few as 35,000 soldiers could control Ethiopia, but it was proved wrong on March 1, 1896, at the Battle of Adowa (Adwa), where General Oreste Baratieri led 14,500 Italian troops on a poorly organized attack against Menilek's well-armed host of some 100,000 fighters. The Italian lines crumbled, and at noon retreat was sounded. The emperor retired into Ethiopia to await negotiations, and on Oct. 26, 1896, he signed the Treaty of Addis Ababa, which abrogated the Treaty of Wichale.

Menilek subsequently directed the Solomonid state into areas never before under its rule. Between 1896 and 1906 Ethiopia expanded to its present size, taking in the highlands, the key river systems, and a buffer of low-lying arid or tropical zones around the state's central core. Revenues from the periphery were used to modernize the new capital of Addis Ababa, to open schools and hospitals, and to build communication networks. Menilek contracted with a French company to construct a railway between Addis Ababa and Djibouti, thus spurring the exploitation of the country's produce by foreign merchants in cooperation with the ruling elites.

The reign of Haile Selassie I. As Menilek aged, he appointed a cabinet to act for his grandson and heir designate, Iyasu, a son of the Oromo ruler of Welo. Upon

the emperor's death in 1913, Iyasu took power in his own right. Seeking a society free of religious and ethnic divisions, he removed many of Menilek's governors and integrated Muslims into the administration, outraging Ethiopia's Christian ruling class. During World War I, Iyasu dallied with Islām and with the Central Powers in the hope of regaining Eritrea. After the Allies formally protested, Addis Ababa's aristocrats met, accused Iyasu of apostasy and subversion, and deposed him on Sept. 27, 1916.

Iyasu was replaced by Menilek's daughter, Zauditu. Since it was considered unseemly for a woman to serve in her own right, Ras Tafari, the son of Ras Makonnen and a cousin of Menilek, served as Zauditu's regent and heir apparent. The prince developed a modern bureaucracy by recruiting the newly educated for government service. He also engineered Ethiopia's entry into the League of Nations in 1923, reasoning that collective security would protect his backward country from aggression. To brighten Ethiopia's external image, he hired foreign advisers for key departments and set about abolishing slavery—a process in which he was helped by Ethiopia's transition to a market economy.

By 1928, when Zauditu named Tafari king, the economy was booming, thanks mainly to the export of coffee. In the countryside, local officials built roads and improved communications, facilitating the penetration of traders and entrepreneurs. Ethiopians remained in charge of the economy, since Tafari forced foreigners to take local partners and maintained tight control over concessions.

On April 1, 1930, Zauditu died and Tafari declared himself emperor. He was crowned Haile Selassie I ("Strength of the Trinity"; his baptismal name) on November 2. In July 1931 the emperor promulgated a constitution that enshrined as law his prerogative to delegate authority to an appointed and indirectly elected bicameral parliament, among other modern institutions. During 1931–34 Haile Selassie instituted projects for roads, schools, hospitals, communications, administration, and public services. The combined effect of these projects was to open the country to the world economy. By 1932 revenues were pouring into Addis Ababa from taxes applied to 25,000 tons of coffee exported each year.

The Italian occupation

Haile Selassie's success convinced Italy's ruler Benito Mussolini to undertake a preemptive strike before Ethiopia grew too strong to oppose Italian ambitions in the Horn of Africa. After an Ethiopian patrol clashed with an Italian garrison at the Welwel oasis in the Ogaden in November–December 1934, Rome began seriously preparing for war. Haile Selassie continued to trust in the collective security promised by the League of Nations. Only on Oct. 2, 1935, upon learning that Italian forces had crossed the frontier, did he order mobilization. During the subsequent seven-month Italo-Ethiopian War, the Italian command used air power and poison gas to separate, flank, and destroy Haile Selassie's poorly equipped armies. The emperor went into exile on May 2, 1936.

For five years (1936–41) Ethiopia was joined to Eritrea and Italian Somaliland to form Italian East Africa. During this period Italy carried out a program of public works, concentrating especially on highways and on agricultural and industrial development. Resistance to the occupation continued, however. The Italians dominated the cities, towns, and major caravan routes, while Ethiopian patriots harried the occupiers and sometimes tested the larger garrison towns. When Italy joined the European war in June 1940, the United Kingdom recognized Haile Selassie as a full ally, and the emperor was soon in Khartoum to help train a British-led Ethiopian army. This joint force entered Gojam on Jan. 20, 1941, and encountered an enemy quick to surrender. On May 5 the emperor triumphantly returned to Addis Ababa. Ignoring the British occupation authorities, he quickly organized his own government.

In February 1945 at a meeting with U.S. president Franklin D. Roosevelt, Haile Selassie submitted memoranda stressing the imperative for recovering Eritrea and thereby gaining free access to the sea. In 1948 and again in 1949, two commissions established by the wartime Allies and by the United Nations reported that Eritrea lacked national consciousness and an economy that could sustain independence. Washington, wishing to secure a communications base in Asmera and naval facilities in Mitsiwa—and also to counter possible subversion in the region—supported Eritrea's federation with Ethiopia. The union took place in September 1952.

During the 1950s Ethiopia's coffee sold well in world markets. Revenues were used to centralize the government, to improve communications, and to modernize urban centres. In November 1955 the emperor promulgated a revised constitution, which permitted parliament to authorize finances and taxes, to question ministers, and to disapprove imperial decrees. The constitution also introduced an elected lower house of parliament, a theoretically independent judiciary, separation of powers, a catalog of human rights, and a mandate for bureaucratic responsibility to the people. At the same time, the emperor retained his power of decree and his authority to appoint the government. Among his ministers, he subtly established competing power factions—a stratagem that had the ultimate effect of retarding governmental cooperation, economic development, and bureaucratic modernization.

Opposition to the monarchy

Some educated officials concluded that the country would move ahead only when the imperial regime was destroyed. In December 1960, while the emperor was abroad, members of the security and military forces attempted a coup d'état. The coup rapidly unraveled, but not before the nation's social and economic problems were described in radical terms. Even then, the emperor ignored the coup's significance; in February 1961 he began to name a new government that reflected the status quo ante by depending on the landowning military, aristocracy, and oligarchy for authority. Haile Selassie showed himself unable to implement significant land reform, and as a result progressives and students opposed the regime. The monarchy gradually lost its credibility, especially as it became embroiled in intractable conflicts in Eritrea and with Somalia.

Somalia's independence in 1960 stimulated Somali nationalists in Ethiopia's Ogaden to rebel in February 1963. When Mogadishu joined the fighting, the Ethiopian army and air force smashed its enemy. Mogadishu's consequent military alliance with the Soviet Union upset the regional balance of power, driving up Ethiopia's arms expenditures and necessitating more U.S. assistance. Meanwhile, an insurrection in Eritrea, which had begun in 1960 mainly among Muslim pastoralists in the western lowlands, came to attract highland Christians disaffected by the government's dissolution of the federation in 1962 and the imposition of Amharic in the schools. At the same time, an increasingly radical student movement in Addis Ababa identified Haile Selassie as an agent of U.S. imperialism and his landowning oligarchs as the enemy of the people. Under the motto of "land to the tiller," the students sought to limit property size and rights, and, by fostering the Leninist notion that nationalities had the right to secede, they gave strength and ideological justification to the Eritrean rebellion.

By the early 1970s one-third of Ethiopia's 45,000 soldiers were in Eritrea, and others were putting down tax rebellions in Balē, Sīdamo, and Gojam. In January 1974 there began a series of mutinies led by junior officers and senior noncommissioned officers, who blamed the imperial elites for their impoverishment and for the country's economic and social ills. For the government, the situation was greatly worsened by drought and famine in the overpopulated and overfarmed north, the denial of which became an international scandal. In June representatives of the mutineers constituted themselves as the Coordinating Committee (Derg) of the Armed Forces, Police, and Territorial Army. Major Mengistu Haile Mariam, of Harer's Third Division, was elected chairman. The Derg proceeded to dismantle the monarchy's institutions and to arrest Haile Selassie's cronies, confidantes, and advisers. It then campaigned against the old and senile emperor, who was deposed on Sept. 12, 1974. In November, after a shootout among members of the Derg, as many as 60 leaders of the old regime were executed. The new government issued a Declaration of Socialism on Dec. 20, 1974.

Socialist Ethiopia. The Derg borrowed its ideology from competing Marxist parties, one of which, the Ethiopian People's Revolutionary Party (EPRP), believed so strongly in civilian rule that it undertook urban guerrilla war against the military rulers. During the ensuing anarchy, Mengistu seized complete power as head of state. He then undertook class warfare against the EPRP, as a result of which thousands of Ethiopia's best-educated and idealistic young people were killed or exiled. At that moment of weakness, in May and June 1977, Somalia's army advanced into the Ogaden. Moscow labeled Mogadishu the aggressor and diverted arms shipments to Ethiopia, where Soviet and allied troops trained and armed a People's Militia, provided fighting men, and reequipped the army. Unable to entice the United States into resupplying its troops, Somalia withdrew in early 1978. Mengistu quickly shifted troops to Eritrea, where, by year's end, the secessionists were pushed back into mountainous terrain around Nak'fa.

The nationalized economy

Mengistu sought to transform Ethiopia into a command state led by a disciplined and loyal party that would control virtually every organ of authority. To this end a land-reform proclamation of 1975 transferred ownership of all land to the state and provided allotments of no more than 25 acres (10 hectares) to individual peasants who farmed the land themselves. Extensive nationalization of industry, banking, insurance, large-scale trade, and extra dwellings completed the reforms and wiped out the economic base of the old ruling class. To implement the reforms, adjudicate disputes, and administer local affairs, peasants' associations were organized in the countryside and precinct organizations (*kebellay*) in the towns. In 1984 the Workers' Party of Ethiopia was formed, with Mengistu as secretary-general, and in 1987 a new parliament inaugurated the People's Democratic Republic of Ethiopia, with Mengistu as president.

Farmers failed to generate the high yields expected from the land reform, mainly because the equitable distribution of land among the members of peasants' associations led to smaller plots, overcultivation, land degradation, and declining harvests. In order to feed Ethiopia's cities and the army, the government tried to force the peasants' associations to deliver grain at below-market prices—a disastrous policy that led to a horrific famine in 1984. With one-sixth of Ethiopia's people at risk of starvation, Western nations made available enough surplus grain to end the crisis by mid-1985. Donors were not so forthcoming for a mammoth population resettlement program that proposed to move people from the drought-prone and crowded north to the west and south, where supposedly surplus lands were available. The Mengistu regime handled the shift callously and did not have the necessary resources to provide proper housing, tools, medical treatment, or food for the 600,000 refugees it moved. Resources were also lacking for a related villagization program, which had the putative aim of concentrating scattered populations into villages where they might receive modern services. As late as 1990 most villages lacked the promised amenities because of resource-draining civil strife in the north.

By 1985–86 the government was embattled throughout most of Eritrea and Tigray, but Mengistu simply stepped up recruitment and asked Moscow for more arms. In December 1987 the EPLF broke through the Ethiopian lines before Nak'fa and continued to wage successful war with weapons captured from demoralized government troops. In early 1988 the EPLF began to coordinate its attacks with the Tigray People's Liberation Front (TPLF), which had long been fighting for the autonomy of Tigray and for the Marxist purity of the Ethiopian revolution. The Soviets refused to ship more arms, and in February 1989 a series of defeats and a worsening lack of weaponry forced the government to evacuate Tigray. The TPLF then organized the largely Amhara Ethiopian People's Democratic Movement. Together, these two groups formed the Ethiopian People's Revolutionary Democratic Front (EPRDF), and their forces easily advanced into Gonder and Welo provinces. The following year the EPLF occupied Mitsiwa; this broke the Ethiopian stranglehold on supplies entering the country and demonstrated that the government no longer ruled in Tigray and Eritrea. Shortly thereafter, when the TPLF cut the Addis Ababa–Gonder road and put Gojam at risk, Mengistu announced the end of socialism.

Collapse of the Derg

The peasantry immediately abandoned the regime's villages for their old homesteads, dismantled cooperatives, and redistributed land and capital goods. They ejected or ignored party and government functionaries, in several cases killing recalcitrant administrators. The regime was thus weakened in the countryside—especially in southern Ethiopia, where the long-dormant Oromo Liberation Front became active. By May 1991, with EPRDF forces controlling Tigray, Welo, Gonder, Gojam, and about half of Shewa, it was obvious that the army did not have sufficient morale, manpower, weapons, munitions, and leadership to stop the rebels' advance on Addis Ababa. Mengistu fled, and on May 28 the EPRDF took power.

The new government, led by a Tigrayan, the EPRDF chairman Meles Zenawi, claimed that it would democratize Ethiopia through recognition of the country's ethnic heterogeneity. No longer would the Ethiopian union be maintained by force; rather, it would be a voluntary federation of its many peoples. To this end the EPRDF and other political groups agreed to the creation of a transitional government that would engineer a new constitution and elections; to a national charter that recognized an ethnic division of political power; and to the right of nationalities to secede from Ethiopia (thus paving the way for Eritrea's legal independence in 1993).

It soon became obvious that the new regime was weakening the central administration of Ethiopia in favour of strong, ethnically based regional governments whose ruling parties were intended to be affiliated politically and ideologically with the EPRDF. A new regional map reflecting the changes was issued in 1992. Some Ethiopians criticized the new ethnic units as similar to an antinational reorganization of Ethiopia drawn up by the Italians in 1936. The Amhara, identified by the EPRDF as colonizers, were particularly affronted by the apparent disunification of the country. The government fought back by denouncing Amhara leaders as antidemocratic chauvinists and by muzzling the press through application of a new law that theoretically guaranteed its freedom. In the provinces, the government did not bother to maintain even the guise of freedom: there, the suppression of anti-EPRDF forces, especially the Oromo Liberation Front, was so blatant as to be noticed by the members of an international team sent to observe regional elections in June 1992. (H.G.M.)

Throughout 1992–93, the transitional government worked with donor governments and the World Bank to forge a structural adjustment program that devalued the Ethiopian currency, sharply reduced government intervention in the economy, and made it easier for foreign companies to invest in Ethiopia and repatriate their profits. However, the government was slow to denationalize land and to return property confiscated by the Derg, and, despite several years of healthy economic growth in the 1990s, there were regional food shortages in 1994 and 1999. The government repeatedly called upon the international donor community for help, but, by failing to free the economy and thus failing to solve its chronic famine crisis, Ethiopia remained unable to finance its own development and to create the surplus needed to relieve its own population.

Ethiopia promulgated a new constitution in 1995 that enshrined the EPRDF concept of regional and ethnic autonomy; yet the central government was able to maintain relatively strong control in most parts of the country, despite unrest from ethnic Somalis and some Islāmic groups. Eritrea maintained warm relations with Ethiopia following its secession, but these deteriorated rapidly in 1998, and war between the two states erupted in May of that year. Despite international efforts at mediation, a truce was not signed until December 2000, and the economic ramifications of this bloody conflict threatened Ethiopia's modest social and economic gains of the previous decade.

Somalia

The Somali Democratic Republic (Somali: Jamhuuriyadda Dimuqraadiga Soomaaliya), a state in the Horn of Africa, occupies an important geopolitical position between sub-Saharan Africa and the countries of Arabia and southwestern Asia. With an area of about 246,000 square miles (637,000 square kilometres), it is bounded on the north by the Gulf of Aden and on the east by the Indian Ocean; from its southern point, its western border is bounded by Kenya and Ethiopia and, to the northwest, by Djibouti. The capital is Mogadishu (in Somali, Muqdisho or Xamar; in the colonial Italian rendering, Mogadiscio).

Living in a country of geographic extremes, with a dry and hot climate and a landscape of thornbush savanna and semidesert, the inhabitants of Somalia have developed equally demanding economic survival strategies. The Somali are Muslim, and about half follow a mobile way of life, pursuing nomadic pastoralism or agropastoralism. As a result, the Somali are an egalitarian, freedom-loving people who are suspicious of governmental authority.

PHYSICAL AND HUMAN GEOGRAPHY

The Somali Peninsula consists mainly of a tableland of young limestone and sandstone formations. Apart from a mountainous coastal zone in the north and several pronounced river valleys, most of the country is extremely flat, with few natural barriers to restrict the mobility of the nomads and their livestock.

Flat topography

The land. *Relief.* In the extreme north, along the Gulf of Aden, is a narrow coastal plain called the Guban. This gives way inland to a maritime mountain range with a steep, north-facing scarp. Near Ceerigaabo (Erigavo), a mountain called Surud Cad (Surud Ad) reaches the highest elevation in the country, about 7,900 feet (2,408 metres). To the south are the broad plateaus of the Galgodon (or Ogo) Highlands and the Sool and Hawd regions.

In southern Somalia the crystalline bedrock outcrops to the south of Baydhabo (Baidoa) in the shape of granite inselbergs. These give way farther south to alluvial plains, which are separated from the coast by a belt of dunes stretching more than 600 miles (1,000 kilometres) from south of Kismaayo (Chisimaio) to north of Hobyo (Obbia).

Drainage. The flatness of the Somalian plateaus is interrupted in the northeast by deep wadis, the Dharoor and Nugaal (Nogal) valleys. In the southwest are the only permanent rivers in Somalia, the Jubba (Giuba) and Shabeelle (Shebele), originating in the Ethiopian highlands. The Jubba carries more water than the Shabeelle, which sometimes dries up in its lower course in years of sparse rainfall in the Ethiopian highlands.

Soil. The types of soil vary according to climate and parent rock. The arid regions of northeastern Somalia have mainly thin and infertile desert soils. The limestone plateaus of the interfluvial area have some areas of fertile, dark gray to brown, calcareous residual soils that provide good conditions for rain-fed agriculture. The most fertile soils (vertisols, or black cotton soils) are found on the alluvial plains of the Jubba and Shabeelle rivers and are mainly used for irrigation agriculture.

Climate. Somalia lies astride the equator and so belongs to the tropics. Unlike typical climates at this latitude, conditions in Somalia range from arid in the northeastern and central regions to semiarid in the northwest and south.

The principal seasons

The climatic year comprises four seasons. The *gu,* or main rainy season, lasts from April to June; the second rainy season, called the *dayr,* extends from October to December. Each is followed by a dry season: the main one (*jilaal*) from December to March and the second one (*xagaa*) from June to September. During the second dry season, showers fall in the coastal zone.

Long-term mean annual rainfall is less than 4 inches (100 millimetres) in the northeast and approximately 8 to 12 inches in the central plateaus. The southwest and northwest receive an average of 20 to 24 inches a year. At Berbera on the northern coast the afternoon high averages more than 100° F (38° C) from June through September. The average afternoon high at Mogadishu ranges from 83° F (28° C) in July to 90° F (32° C) in April.

Plant and animal life. In accordance with rainfall distribution, southern and northwestern Somalia have a relatively dense thornbush savanna, with various succulents and species of acacia. By contrast, the high plateaus of northern Somalia have wide, grassy plains, with mainly low formations of thorny shrubs and scattered grass tussocks in the remainder of the region. Northeastern Somalia and large parts of the northern coastal plain, on the other hand, are almost devoid of vegetation. Exceptions to this are the wadi areas and the moist zones of the northern coastal mountains, where the frankincense tree (*Boswellia*) grows. The myrrh tree (*Commiphora*) thrives in the border areas of southern and central Somalia.

Owing to inappropriate land use, the original vegetation cover, especially in northern Somalia, has been heavily degraded and in various places even entirely destroyed. This progressive destruction of plant life also has impaired animal habitats and reduced forage, affecting not only Somalia's greatest resource, its livestock (chiefly goats, sheep, camels, and cattle), but also the wildlife. At present there are still many species of wild animals throughout the country—especially in the far south: hyenas, foxes, leopards, lions, warthogs, ostriches, small antelopes, and a large variety of birds.

Settlement patterns. Roughly half of the Somali population lives permanently in settled communities, the other half being nomadic pastoralists or agropastoralists. The settlements of the sedentary population consist of large, clustered villages near the rivers and in the central interfluvial area, as well as small hamlets farther away. The population is also concentrated in the old trading centres on the coast, such as Kismaayo, Baraawe (Brava), Marka (Merca), Mogadishu, Berbera, and Boosaaso (Bosaso).

The strong influence from Arabia, Persia, and India has shaped the face of the old coastal town centres, and Italian colonial architecture is visible in Mogadishu. There are two main types of traditional house: the typically African round house (*mundul*), mainly found in the interior, and the Arab-influenced rectangular house (*cariish*) with corrugated-steel roof, prevailing in the coastal regions and northern Somalia.

Pastoral nomads still live in transportable round huts called *aqal.* During the dry seasons, the high mobility of these livestock keepers leads to their temporary concentration in the river valleys of southern Somalia and around important water points all over the country.

Heavy migration from rural areas into towns has caused enormous urban expansion, especially in Mogadishu. As a result of increased market-oriented and extrapastoral activities, more nomads are tending to adopt a semi-settled

Michael S. Yamashita

Nomads drawing water from a well, Somalia.

way of life and economy. This has led to a great number of permanent nomad settlements, chiefly along the roads and tracks of the country's interior.

The people. In culture, language, and way of life, the people of Somalia, northeastern Kenya, the Ogaden region of Ethiopia, and the southern part of Djibouti are largely one homogeneous group.

Ethnic composition. The Somali people are divided into numerous clans, which are groups that trace their common ancestry back to a single father. These clans, which in turn are subdivided into numerous subclans, combine at a higher level to form clan families. The clan families inhabiting the interfluvial area of southern Somalia are the Rahanwayn and the Digil, which together are known as the Sab. Mainly farmers and agropastoralists, the Sab include both original inhabitants and numerous Somali groups that have immigrated into this climatically favourable area. Other clan families are the Daarood of northeastern Somalia, the Ogaden, and the border region between Somalia and Kenya; the Hawiye, chiefly inhabiting the area on both sides of the middle Shabeelle and south-central Somalia; and the Isaaq, who live in the central and western parts of northern Somalia. In addition, there are the Dir, living in the northwestern corner of the country but also dispersed throughout southern Somalia, and the Tunni, occupying the stretch of coast between Marka and Kismaayo. Toward the Kenyan border the narrow coastal strip and offshore islands are inhabited by the Bagiunis, a Swahili fishing people.

As well as the Somali, there is a sizable and economically important Bantu population, which is mainly responsible for the profitable irrigation agriculture practiced on the lower and middle reaches of the Jubba and Shabeelle rivers. Socially, however, they are regarded as inferior, many of them being descendants of former slaves. The result is a strict social distinction between the "noble" Somali of nomadic descent and the Bantu groups.

Arabs and Europeans

Another economically significant minority is the several tens of thousands of Arabs, mainly of Yemenite origin. By the end of the 1980s, the number of Italians permanently residing in Somalia (mainly as banana farmers) had dropped to only a few hundred.

Linguistic composition. The Somali language belongs to the Cushitic language family. Despite several regional dialects, it is understood throughout the country. The second official language is Arabic, which is spoken chiefly in northern Somalia and in the coastal towns. Owing to Somalia's colonial past, many people have a good command of English and Italian, which also are used in colleges and in the university. Swahili also is spoken in the south.

In 1973 Somalia adopted an official orthography based on the Latin alphabet. Until then, Somali had been an unwritten language.

Religion. Most Somali belong to the Shāfiʿī rite of the Sunnite sect of Islām. Various Muslim orders (*ṭarīqa*) are important, especially the Qādirīyah, the Aḥmadīyah, and the Ṣaliḥiyah.

Demographic trends. The population of Somalia has been increasing annually by more than 3 percent, despite very high infant mortality and an average life expectancy of less than 50 years.

A high migration rate into the towns, chiefly by young men, has led to a disproportionately large percentage of old people in most rural areas and to high unemployment in the towns. Also, after the Ogaden conflict of 1977–78, hundreds of thousands of Somali from Ethiopia fled to Somalia, and during the ensuing civil war more than one million Somali sought shelter in neighbouring countries.

The economy. Somalia's economy is based on agriculture; however, the main economic activity is not crop farming but livestock raising. Between 1969 and the early 1980s, the military government imposed a system of "Scientific Socialism," which featured the nationalization of banks, insurance firms, oil companies, and all large industrial firms, the setting up of state-owned enterprises, farms, and trading companies, and the organizing of state-controlled cooperatives. In the end, this experiment weakened the Somalian economy considerably, and since the collapse of the military regime the economy has suffered even more as a result of civil war. Generally speaking, the Somalian economy cannot survive without foreign aid.

Resources. Somalia has few mineral resources—only some deposits of tin, phosphate, gypsum, guano, coal, iron ore, and uranium—but both quantity and quality are too low for mining to be worthwhile. However, the deposits of the clay mineral sepiolite, or meerschaum, in south-central Somalia are among the largest known reserves in the world. Exploitable oil and natural gas have not yet been found. Sea salt is collected at several sites on the coast.

Agriculture. By far the most important sector of the economy is agriculture, with livestock raising surpassing crop growing fourfold in value and earning about 90 percent of Somalia's foreign exchange. Agriculture in Somalia can be divided into three subsectors. The first is nomadic pastoralism, which is practiced outside the cultivation areas. This sector, which raises goats, sheep, camels, and cattle, has become increasingly market-oriented. The second sector is the traditional, chiefly subsistence, agriculture practiced by small farmers. This traditional sector takes two forms: rain-fed farming in the south and northwest, which raises sorghum, often with considerable livestock; and small irrigated farms along the rivers, which produce corn (maize), sesame, cowpeas, and, near towns, vegetables and fruits. The third sector consists of market-oriented farming on medium- and large-scale irrigated plantations along the lower Jubba and Shabeelle rivers. Here the major crops are bananas, sugarcane, rice, cotton, vegetables, grapefruit, mangoes, papayas, and other fruits.

Importance of livestock raising

Forestry. The acacia species of the thorny savanna in southern Somalia supply good timber and are the major source of charcoal, but charcoal production has long exceeded ecologically acceptable limits. More efficient and careful handling of *Boswellia, Commiphora,* and other resin-exuding trees could increase yields of aromatic gums.

Fishery. In the small fishing sector, tunny and mackerel are caught and canned in the north, sharks are often caught and sold dried by artisanal inshore fishers, and, in southern Somalia, choice fish and shellfish are processed for export.

Industry. In the late 1980s industry was responsible for just under 10 percent of Somalia's gross domestic product. Mogadishu was the chief industrial centre, with bottling plants, factories producing spaghetti, cigarettes, matches, and boats, a petroleum refinery, a small tractor assembly workshop, and small enterprises producing construction materials. In Kismaayo there were a meat-tinning factory, a tannery, and a modern fish factory. There were two sugar refineries, one near Jilib on the lower reach of the Jubba and one at Jawhar (Giohar) on the middle reach of the Shabeelle.

Low industrial production

Even before the destruction caused by Somalia's civil wars of the 1980s and '90s, the productivity of Somalian factories was very low. Often entire works did not operate at full capacity or produced nothing at all over long periods. A significant portion of commodities necessary for daily life is produced by small workshops in the informal sector.

Finance. The three principal banks, which are nationalized, are the Central Bank of Somalia, the Commercial and Savings Bank of Somalia, and the Somali Development Bank, which mainly provides loans for development projects. The currency, the Somali shilling, has been depreciating for years, and a shortage of hard currency greatly impedes the country's economic development.

Trade. Somalia has a large trade deficit. Its chief export commodities are livestock (to Arab countries, mainly Saudi Arabia) and bananas (to Italy and Arab countries). Other, much less important exports are hides and skins, fish, and frankincense and myrrh. Almost everything is imported, even food for an urban population no longer accustomed to the traditional diet.

Besides the official market, there is also a flourishing black market. Since wages in Somalia are very low, almost every family is directly or indirectly involved in informal trading.

Transportation. Inadequate transport facilities are a considerable impediment to Somalia's economic develop-

ment. There are no railways. Only about 1,800 miles of paved roads are passable year-round, and in the rainy seasons most rural settlements are not accessible by motor vehicle. Buses, trucks, and minibuses are the main means of transport for the population.

During peacetime, the state-owned Somali Airlines operated on national routes as well as on international routes to Kenya, Arabia, and Europe. Mogadishu, Berbera, and Kismaayo all have airports with long runways. These three cities also have deep-water harbours, but dangerous coral reefs keep coastal traffic to a minimum.

Administration and social conditions. *Government.* In 1960 Somalia became independent as a Western-style parliamentary democracy. A military coup in 1969, led by Major General Maxamed Siyaad Barre, inaugurated a phase of "Scientific Socialism." There existed one legal political party, the Somali Revolutionary Socialist Party, and various socialist-style mass organizations. Under the 1979 constitution the president and his supporters held the important positions of power, and a People's Assembly had no real power.

After years of destructive civil war waged by clan-based guerrillas, Siyaad's government fell in January 1991. In the north a de facto government declared the formation of an independent Somaliland Republic, while the fragmented, conflict-riven south lay largely in the hands of various clan militias. In 1993 the United Nations Operation in Somalia (UNOSOM II), consisting of military units from 26 countries and commanded by a special envoy from the United Nations, began an effort to stop the fighting and secure agreement on an interim government.

Education. Traditionally, Qur'ānic schools are responsible for the religious education of children according to Islāmic law. In addition, there is the state educational system, which, on the whole, is successful despite considerable shortcomings.

After primary school, students have a chance to attend agricultural secondary schools, a polytechnical school, a vocational training centre, a teachers' training centre, an agricultural college, or the National University, most of these institutions being located in and around Mogadishu.

Health and welfare. In spite of various health campaigns, the health service in Somalia is totally inadequate. Hospitals and dispensaries are located mainly in Mogadishu and, to a limited extent, in the district and provincial capitals.

Social services supplied by the state have fallen far short of demand. However, even in the towns the social network of family relationships is still intact and is of great help in times of need.

Cultural life. The varied cultural life of the Somali includes both traditional activities and, especially in the towns, many modern interests.

Daily life. Cultural activities primarily consist of poetry, folk dancing, the performance of plays, and singing. These traditional activities still retain their importance, especially in rural areas, and are practiced not only at family and religious celebrations but also at state ceremonies. On such occasions traditional local costume is generally worn.

Traditional and modern culture

Especially in the towns, traditional culture is rapidly being superseded by imported modern influences, such as television and videotapes, cinema, and bars and restaurants. Urban Somalian cooking has been strongly influenced by Italian cuisine, and young townspeople are much influenced by Western fashion in the way they dress. Association football (soccer) is a very popular sport.

The arts. There are many famous Somali artists, poets, musicians, actors, and dancers, some of whom live in exile. Nuruddin Farah, whose novels are written in English, has achieved international fame.

Cultural institutions in Mogadishu are the National Museum, the new Historical Museum, and the National Theatre. The Somali Academy of Sciences and Arts promotes research on Somalia.

Press and broadcasting. Press, radio, and television are all controlled and censored by the state. Books in general are hard to obtain, and the printing quality of the few books available in Somali is very poor. (J.H.A.J.)

For statistical data on the land and people of Somalia, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Before partition. *Early peoples of the coasts and hinterland.* From their connection with the Ethiopian hinterland, their proximity to Arabia, and their export of precious gums, ostrich feathers, ghee (clarified butter), and other animal produce as well as slaves from farther inland, the northern and eastern Somali coasts have for centuries been open to the outside world. This area probably formed part of Punt, "the land of aromatics and incense," mentioned in ancient Egyptian writings. Between the 7th and 10th centuries, immigrant Muslim Arabs and Persians developed a series of trading posts along the Gulf of Aden and Indian Ocean coasts. Islām became firmly established in the northern ports of Seylac (Zeila) and Berbera and at Marka, Baraawe, and Mogadishu on the Indian Ocean coast in the south. These centres were engaged in a lively trade, with connections as far afield as China.

Probably by the 10th century the country from the Gulf of Aden coast inland was occupied first by Somali nomads and then, to their south and west, by various groups of pastoral Oromo who apparently had expanded from their traditional homelands in southwestern Ethiopia. To the south of these Cushitic-speaking Somali and Oromo—the "Berberi" of classical times and of the Arab geographers—the fertile lands between the Shabeelle and Jubba rivers were occupied, partly at least, by sedentary Bantu tribes of the Nyika confederacy, whose ancient capital was Shungwaya. Remnants of these Zanj, as they were known to the Arab geographers, still survive in this region, but their strongest contemporary representatives are found among the coastal Bantu, of whom the Pokomo live along the Tana River in northern Kenya. Another smaller allied population consisted of the ancestors of the scattered bands of hunters of northern Kenya and southern Somalia known as Wa-Ribi, or Wa-Boni, a people whose appearance and mode of existence recall those of the San.

The great Somali migrations. With this distribution of peoples in the 10th century, the stage was set for the great movements of expansion of the Somali toward the south and of the Oromo to the south and west. The first known major impetus to Somali migration was that of Sheikh Ismail Jabarti, ancestor of the Daarood Somali, who apparently came from Arabia to settle in the northeastern corner of the Somali Peninsula in the 11th century. This was followed, perhaps two centuries later, by the settlement of Sheikh Isaq, founder of the Isaaq Somali. As the Daarood and Isaaq clans grew in numbers and territory in the northeast, they began to vie with their Oromo neighbours, thus creating a general thrust toward the southwest. By the 16th century the movements that followed seem to have established much of the present distribution of Somali clans in northern Somalia. Other Somali pressed farther south, and some, according to the Arab geographer Ibn Said, had already reached the region of Marka by as early as the 13th century.

Somali pressure on the Oromo

In the meantime, farther to the west, a ring of militant Muslim sultanates had grown up around the Christian kingdom of Ethiopia, and the two sides were engaged in a protracted struggle for supremacy. Somali clansmen regularly formed part of the Muslim armies: the name Somali first occurs in an Ethiopian song of victory early in the 15th century. In the 16th century the Muslim state of Adal, whose port was Seylac, assumed the lead in the holy wars against the Christian Amhara. The turning point in the struggle between Christians and Muslims was reached with the Ethiopian victory in 1542, with Portuguese support, over the remarkable Muslim leader Aḥmad ibn Ibrāhīm al-Ghāzī, known to the Ethiopians as Aḥmad Grāñ. With his Somali armies, Aḥmad had harried Ethiopia almost to the point of collapse. This victory, which saved Ethiopia, also closed the door to Somali expansion westward and increased the pressure of the Somali and Oromo thrust southward. With this stimulus the main mass of the Oromo swept into Ethiopia from the south and southwest and streamed in conquering hordes as far north as the ancient city of Harer, which was laid to waste in 1567.

This massive invasion left something of a political vacuum in the south of the Horn, which new Somali settlers were quick to fill. By the 17th century the influx of new migrants, competing and jostling with each other, had become considerable. The old Ajuran Somali sultanate, linked with the port of Mogadishu, was overthrown and Mogadishu itself invaded and split into two rival quarters. Some of the earlier Somali groups found refuge in northern Kenya. The continuing Somali thrust south—largely at the expense of Oromo and Zanj predecessors—was ultimately only effectively halted at the Tana River by the establishment of administrative posts about 1912.

Somali clans and foreign traders. Thus, by the latter part of the 19th century the coastal and hinterland traditions had merged, and the centre of pressure had swung from the coast to the interior. In the north the ancient ports of Berbera and Seylac, much reduced in prosperity and importance, were now controlled by Somali nomads, and the position with the old ports of Marka, Baraawe, and Mogadishu was very similar. These towns had all been penetrated by various Somali clans, and the dominant political influence became that exercised by the Geledi clan ruling the lower reaches of the Shabeelle. Commercial and political links that provided an opening for European infiltration had, however, also been forged between these two coasts and the outside world. Part of the northern Somali coast including Seylac was then nominally under Turkish suzerainty, the Turkish claim going back to the 16th century, when Turkish forces had aided Aḥmad Grāñ in his campaigns against Ethiopia. The southern coastal towns, on the other hand, acknowledged the overlordship of the sultan of Zanzibar, although the latter's authority was slight in comparison with that exercised locally by the Geledi Somali.

The imperial partition. *Competition among the European powers and Ethiopia.* About the middle of the 19th century the Somali Peninsula became a theatre of competition between Great Britain, Italy, and France. On the African continent itself Egypt also was involved, and later Ethiopia, expanding and consolidating its realm under the guiding genius of the emperors Tewodros II, Yohannes IV, and Menilek II. Britain's interest in the northern Somali coast followed the establishment in 1839 of the British coaling station at Aden on the short route to India. The Aden garrison relied upon the importation of meat from the adjacent Somali coast. France sought its own coaling station and obtained Obock on the Afar coast in 1862, later thrusting eastward and developing the Somali port of Djibouti. Farther north, Italy opened a station in 1869 at Aseb, which, with later acquisitions, became the colony of Eritrea.

Stimulated by these European maneuvers, Egypt revived Turkey's ancient claims to the Red Sea coast. In 1870 the Egyptian flag was raised at Bullaxaar (Bulhar) and Berbera. With the disorganization caused by the revolt in the Sudan, however, Egypt was obliged to curtail its colonial responsibilities, evacuating Harer and its Somali possessions in 1885. In these circumstances the British government reluctantly decided to fill the gap left by Egypt. Between 1884 and 1886, accordingly, treaties of protection were drawn up with the main northern Somali clans guaranteeing them their "independence." Somali territory was not fully ceded to Britain, but a British protectorate was proclaimed and vice-consuls appointed to maintain order and control trade at Seylac, Berbera, and Bullaxaar. The interior of the country was left undisturbed.

Meanwhile, France had been assiduously extending its colony from Obock, and a clash with Britain was only narrowly averted when an Anglo-French agreement on the boundaries of the two powers' Somali possessions was signed in 1888. In the same period, the Italians were also actively extending their Eritrean colony and encroaching upon Ethiopian territory. Not to be outdone, Menilek took the opportunity of seizing the Muslim city of Harer, left independent after the Egyptian withdrawal. In 1889 Ethiopia and Italy concluded the Treaty of Wichale, which in the Italian view established an Italian protectorate over Ethiopia. Arms and capital were poured into the country, and Menilek was able to apply these new resources to bring pressure to bear on the Somali clansmen around Harer. In 1889 Italy also acquired two protectorates in the northeastern corner of Somalia; and by the end of the year the southern part of the Somali coast leased by the British East Africa Company from the sultan of Zanzibar was sublet to an Italian company.

Italian rule in the south

Italy had thus acquired a Somali colony. From 1892 the lease was held directly from Zanzibar for an annual rent of 160,000 rupees, and, after the failure of two Italian companies by 1905, the Italian government assumed direct responsibility for its colony of Italian Somaliland. To the south of the Jubba River the British East Africa Company held Jubaland until 1895, when this became part of Britain's East Africa protectorate. Britain and Italy reached agreement in 1884 on the extent of their respective Somali territories, but the Battle of Adwa (1896), at which the infiltrating Italian armies were crushed by Ethiopian forces, radically changed the position. Ethiopia, then independent of Italy, was plainly master of the hinterland, and in 1896–97 Italy, France, and Britain all signed treaties with Emperor Menilek, curtailing their Somali possessions. Italy gave up the Somali Ogaden, and Britain excised much of the western Hawd from its protectorate. Although the land and the Somali clansmen (who were not consulted), so abandoned, were not recognized as belonging to Ethiopia, there was nothing then to stop their gradual acquisition by Ethiopia.

Revolt in British Somaliland. These arrangements had scarcely been completed when the British Somaliland protectorate administration found its modest rule threatened by a religious rebellion led by Maxamed Cabdulle Xasan (in Arabic, Muḥammad ibn ʿAbd Allāh Ḥasan). This Somali sheikh (known to the British as the Mad Mullah) of the Ogaadeen clan, living with his mother's people in the east of the protectorate, was an adherent of the Ṣaliḥiyah religious order, whose reformist message he preached with messianic zeal.

Sayyid Maxamed

Maxamed assumed the title of sayyid (lord), and his followers were known as the dervishes. He displayed great skill in employing all the traditional tactics of Somali clan politics in building up his following, strengthening these with the call to national Muslim solidarity against the infidel colonizers. Arms and ammunition, denied to Somali in the past, became easily available through the ports of Djibouti and the northeastern coast, and the dervishes, although opposed by many Somali, who were branded as traitors to Islām, successfully weathered four major British, Italian, and Ethiopian campaigns between 1900 and 1904. The cumbersome British armies, hampered by their supply and water requirements, found the dervish guerrilla tactics hard to combat effectively. A new policy was subsequently adopted, however, and, with the aid of an increasingly effective camel constabulary (whose founder, Richard Corfield, was killed at the Battle of Dulmadoobe in 1913), the dervishes were kept at bay until 1920, when a combined air, sea, and land operation finally routed them. The formidable dervish stronghold at Taleex, or Taleh, was bombed, but the sayyid escaped, as so often before, only to die of influenza a few months later while desperately seeking to rally his scattered followers.

Italian Somaliland. In Italian Somaliland, where the Italians had been gradually extending their hold on the country, the sayyid's rebellion had caused less disruption, and the appointment in 1923 of the first fascist governor marked a new active phase in the life of the colony. Two years later Britain ceded Jubaland with the port of Kismaayo, and in 1926, after a bitter military campaign, the two northern Italian protectorates were firmly incorporated. Italian settlement was encouraged, and fruit plantations were developed along the Shabeelle and Jubba valleys. Although agreements of 1897 and 1908 had defined the border with Ethiopia, this had not been demarcated, except for a stretch of about 18 miles delimited in 1910, and remained in dispute, thus facilitating the gradual Italian infiltration into Ethiopia. In 1934 the celebrated Welwel incident occurred in the eastern part of the Ogaden claimed by both Italy and Ethiopia. The Italian conquest of Ethiopia that followed brought the Ethiopian and Italian Somali territories together within the frame-

work of Italy's short-lived East African empire. Italian Somaliland became the province of Somalia.

The Somali Republic. *Independence and union.* During World War II the British protectorate was evacuated (1940) but was recaptured with Italian Somalia in 1941, when Ethiopia also was liberated. With the exception of French Somaliland, all the Somali territories were then united under British military administration. In 1948 the protectorate reverted to the Colonial Office; the Ogaden and the Hawd were gradually surrendered to Ethiopia; and in 1950 the Italians returned to southern Somalia with 10 years to prepare the country for independence under a United Nations trusteeship.

The British protectorate became independent on June 26, 1960. On July 1, Italian Somalia followed suit, and the two territories joined as the Somali Republic. The politics of the new republic were conditioned by clan allegiances, but the first major problems arose from the last-minute marriage between the former Italian trust territory and the former British protectorate. Urgent improvements in communication between the two areas were necessary, as were readjustments in their legal and judicial systems. The first independent government was formed by a coalition of the southern-based Somali Youth League (SYL) and the northern-based Somali National League (SNL).

Pan-Somalism. While modest developments were pursued internally with the help of mainly Western aid, foreign policy was dominated by the Somali unification issue and by the campaign for self-determination of adjoining Somali communities in the Ogaden, French Somaliland, and northern Kenya. The Somalian government strongly supported the Kenyan Somali community's aim of self-determination (and union with Somalia); when this failed in the spring of 1963, after a commission of inquiry endorsed Somali aspirations, Somalia broke off diplomatic relations with Britain and a Somali guerrilla war broke out in northern Kenya, paralyzing the region until 1967. By the end of 1963 a Somali uprising in the Ogaden led to a brief confrontation between Ethiopian and Somalian forces. Since the United States and the West provided military support to Ethiopia and Kenya, Somalia turned to the Soviet Union for military aid. Nevertheless, the republic maintained a generally neutral, but pro-Western, stance, and, indeed, a new government formed in June 1967 under the premiership of Maxamed Xaaji Ibrahiim Cigaal (Muhammad Haji Ibrahim Egal) embarked on a policy of détente with Kenya and Ethiopia, muting the Pan-Somali campaign.

The era of "Scientific Socialism." In March 1969 more than 1,000 candidates representing 64 parties (mostly clan-based) contested the 123 seats in the National Assembly. After these chaotic elections, all the deputies (with one exception) joined the SYL, which became increasingly authoritarian. The assassination of President Cabdirashiid Cali Sherma'arke (Abdirashid Ali Shermarke) on Oct. 15, 1969, provoked a government crisis, of which the military took advantage to stage a coup d'état on October 21.

Maxamed Siyaad Barre

The overthrow of Cigaal brought to power as head of state and president of a new Supreme Revolutionary Council the commander of the army, Major General Maxamed Siyaad Barre (Muḥammed Siad Barre). At first the new regime concentrated on consolidating its power internally. Siyaad quickly adopted "Scientific Socialism," which, he claimed, was fully compatible with his countrymen's traditional devotion to Islām. Relations with socialist countries (especially the Soviet Union and China) were so greatly strengthened at the expense of Western connections that, at the height of Soviet influence, slogans proclaimed a trinity of "Comrade Marx, Comrade Lenin, and Comrade Siyaad." Rural society was integrated into this totalitarian structure through regional committees on which clan elders (now renamed "peace-seekers") were placed under the authority of a chairman, who was invariably an official of the state apparatus. Clan loyalties were officially outlawed, and clan-inspired behaviour became a criminal offense. Of the government's many "crash programs" designed to transform society, the most successful were mass literacy campaigns in 1973 and 1974, which made Somali a written language (in Latin characters) for the first time.

After 1974 Siyaad turned his attention to external affairs. Somalia joined the Arab League, gaining much-needed petrodollar aid and access to political support from those Persian Gulf states to which Somali labour and livestock were exported at a growing rate. Following Haile Selassie's overthrow in September 1974, Ethiopia began to fall apart, and guerrilla fighters of the Western Somali Liberation Front (WSLF) in the Ogaden pressed Siyaad (whose mother was an Ogaadeen) for support. When in June 1977 France granted independence to Djibouti (under a Somali president), the WSLF, backed by Somalia, immediately launched a series of fierce attacks on Ethiopian garrisons. By September 1977 the war was at the gates of Harer. Then the Soviet Union turned to fill the superpower vacuum left in Ethiopia by the gradual withdrawal of the United States. In the spring of 1978, with the support of Soviet equipment and Cuban soldiers, Ethiopia reconquered the Ogaden, and hundreds of thousands of Somali refugees poured into Somalia.

This terrible reversal strained the stability of the regime as the country faced a surge of clan pressures. An abortive military coup in April 1978 paved the way for the formation of two opposition groups: the Somali Salvation Democratic Front (SSDF), drawing its main support from the Majeerteen clan of the Mudug region in central Somalia, and the Somali National Movement (SNM), based on the Isaaq clan of the northern regions. Formed in 1982, both organizations undertook guerrilla operations from bases in Ethiopia. These pressures, in addition to pressure from Somalia's Western backers, encouraged Siyaad to improve relations with Kenya and Ethiopia. But a peace accord (1988) signed with the Ethiopian leader, Mengistu Haile Mariam, obliging each side to cease supporting Somali antigovernment guerrillas, had the ironic effect of precipitating civil war in Somalia.

Clan war. Threatened with the closure of their bases in Ethiopia, the SNM attacked government forces in their home region, while Ogaadeen Somali, who had been progressively absorbed into the army and militia, felt betrayed by the peace agreement with Ethiopia and began to desert, attacking Siyaad's clansmen. Siyaad became preoccupied with daily survival and consolidated his hold on Mogadishu. Clan-based guerrilla opposition groups multiplied rapidly, following the example of the SSDF and SNM. In January 1991, forces of the Hawiye-based United Somali Congress (USC) led a popular uprising that overthrew Siyaad and drove him to seek asylum among his own clansmen. Outside Mogadishu, all the main clans with access to the vast stores of military equipment in the country set up their own spheres of influence. In May 1991 the SNM, having secured control of the former British Somaliland northern region, declared an independent "Somaliland Republic." Government in the south had largely disintegrated and existed only at the local level in the SSDF-controlled northeast region. In Mogadishu the precipitate appointment of a USC interim government triggered a bitter feud between rival Hawiye clan factions. The forces of the two rival warlords, General Maxamed Farax Caydiid (Muḥammad Farah Aydid) and Cali Mahdi Maxamed (Ali Mahdi Muḥammad), tore the capital apart and battled with Siyaad's regrouped clan militia, the Somali National Front, for control of the southern coast and hinterland. This brought war and devastation to the grain-producing region between the rivers, spreading famine throughout southern Somalia. Attempts to distribute relief food were undermined by systematic looting and rake-offs by militias. In December 1992 the United States led a multinational force of more than 35,000 troops, which imposed an uneasy peace on the principal warring clans and pushed supplies into the famine-stricken areas. The military operation provided support for a unique effort at peacemaking by the United Nations. In January and March 1993, representatives of 15 Somali factions signed peace and disarmament treaties in Addis Ababa, but by June the security situation had deteriorated. American and European forces, suffering an unacceptable number of casualties, were withdrawn by March 1994. The UN force was reduced to military units from mainly Third World countries, and the clan-based tensions that had

The United Somali Congress

precipitated the civil war remained unresolved. (I.M.L.)

For later developments in the history of Somalia, see the BRITANNICA BOOK OF THE YEAR.

BIBLIOGRAPHY

The land and economy of eastern Africa. *Africa South of the Sahara* (annual) includes updated essays on all aspects of the countries of eastern Africa. Comprehensive overviews of Kenya, Uganda, and Tanzania are given in W.T.W. MORGAN, *East Africa* (1973); and W.T.W. MORGAN (ed.), *East Africa: Its Peoples and Resources*, 2nd ed. (1972). Plant life of the region is covered in E.M. LIND and M.E.S. MORRISON, *East African Vegetation* (1974); and D.J. PRATT and M.D. GWYNN (eds.), *Rangeland Management and Ecology in East Africa* (1977). The lakes are described in L.C. BEADLE, *The Inland Waters of Tropical Africa*, 2nd ed. (1981); and the rift valleys and their setting are explained in B.H. BAKER, P.A. MOHR, and L.A.J. WILLIAMS, *Geology of the Eastern Rift System of Africa* (1972). The anomalous climate of this portion of Africa is outlined in ch. 7 of GLENN T. TREWARTHA, *The Earth's Problem Climates*, 2nd ed. (1981).

Economic development is best treated in country-by-country accounts or continental overviews, such as *Accelerated Development in Sub-Saharan Africa: An Agenda for Action* (1982), a World Bank study. (W.T.W.M.)

The people of eastern Africa. GEORGE MURDOCK, *Africa: Its Peoples and Their Culture History* (1959), covers all the African peoples. JOCELYN MURRAY (ed.), *Cultural Atlas of Africa* (1981), is also helpful. A large series of slim but densely factual volumes, "Ethnographic Survey of Africa" (1950–), covers the entire region in two sections: "East Central Africa" and "North Eastern Africa."

East Africa: JOHN D. KESBY, *The Cultural Regions of East Africa* (1977), groups the peoples of East Africa and neighbouring areas into cultural regions and attempts to identify the processes by which cultural differences have arisen. LUCY MAIR, *Primitive Government: A Study of Traditional Political Systems in Eastern Africa*, rev. ed. (1977), studies the social organization of the best-documented of the peoples for the period 1890–1960, concentrating on obligations and the settling of disputes.

There are many studies of individual peoples. L.S.B. LEAKEY, *The Southern Kikuyu Before 1903*, 3 vol. (1977), is a detailed example, covering the southern third of one of the most numerous peoples of the Eastern Rift region. Other studies include ANDREW FEDDERS, *Peoples and Cultures of Kenya* (1979); JOHN LAMPHEAR, *The Traditional History of the Jie of Uganda* (1976); and J.C.D. LAWRANCE, *The Iteso: Fifty Years of Change in a Nilo-Hamitic Tribe of Uganda* (1957). (J.D.K.)

The Horn of Africa: JAN BRØGGER, *Belief and Experience Among the Sidamo* (1986), analyzes destiny, illness, and the spirit cult in Sidamo religion in relation to their economy. ASMAROM LEGESSE, *Gada: Three Approaches to the Study of African Society* (1973), gives the most comprehensive account of the *gada* system. DONALD N. LEVINE, *Wax & Gold: Tradition and Innovation in Ethiopian Culture* (1965, reprinted 1986), offers a thorough and detailed study of the culture and ethos of the politically dominant Amhara; his *Greater Ethiopia: The Evolution of a Multiethnic Society* (1974), explores cultural parallels and connections among the many different ethnic groups of the Ethiopian "mosaic." J. SPENCER TRIMINGHAM, *Islam in Ethiopia* (1952, reissued 1965), is a comprehensive cultural history of the Horn of Africa.

I.M. LEWIS, *Blood and Bone: The Call of Kinship in Somali Society* (1994), studies Somali society and culture and the linkages between "traditional" and modern political organization. (I.M.L.)

The history of eastern Africa. J.D. FAGE and ROLAND OLIVER (eds.), *The Cambridge History of Africa*, 8 vol. (1975–86), contains useful chapters on eastern African history, with comprehensive bibliographies. The contributions in UNESCO INTERNATIONAL SCIENTIFIC COMMITTEE FOR THE DRAFTING OF A GENERAL HISTORY OF AFRICA, *General History of Africa* (1981–), are also informative. (Ed.)

East Africa: BETHWELL A. OGOT (ed.), *Zamani: A Survey of East African History*, new ed. (1974), is still the best single-volume survey. ROLAND A. OLIVER *et al.* (eds.), *History of East Africa*, 3 vol. (1963–76), constitutes the most ambitious account so far. P.L. SHINNIE (ed.), *The African Iron Age* (1971), contains authoritative articles on archaeology by H.N. CHITTICK, "The Coast of East Africa," ch. 5, and by J.E.G. SUTTON, "The Interior of East Africa," ch. 6. G.S.P. FREEMAN-GRENVILLE, *The Medieval History of the Coast of Tanganyika* (1962), although subject now to correction, is still valuable. C.S. NICHOLLS, *The Swahili Coast: Politics, Diplomacy, and Trade on the East African Littoral, 1798–1856* (1971), is a very full study. FREDERICK COOPER, *Plantation Slavery on the East Coast of Africa* (1977), provides an excellent socioeconomic study of Zanzibar and Kenya in the 19th century. R.M.A. VAN ZWANENBERG and ANNE KING, *An Economic History of Kenya and Uganda, 1800–1970* (1975), concentrates on the years after 1900. (D.A.Lo./Ed.)

The Horn of Africa: The only book to deal with the history of this region is JOHN MARKAKIS, *National and Class Conflict in the Horn of Africa* (1987). Since there is no established historiography, the history of the entire Horn must be constructed from works devoted to Somalia and Ethiopia; see those sections below. I.M. LEWIS (ed.), *Nationalism & Self Determination in the Horn of Africa* (1983), discusses the rival ethnic nationalisms of the Horn, including those at the centre and periphery of Ethiopia. Works on the history of the Somali-Ethiopian conflict include TOM J. FARER, *War Clouds on the Horn of Africa: The Widening Storm*, 2nd rev. ed. (1979); and ROBERT F. GORMAN, *Political Conflict on the Horn of Africa* (1981), which highlights the Ogaden war of 1977–78. (H.G.M.)

The countries of East Africa. *Kenya:* An up-to-date source of general information, *Kenya: An Official Handbook* (1988), was published on the 25th anniversary of independence. GUY ARNOLD, *Modern Kenya* (1981), gives a general survey of the country and its politics. FRANCIS F. OJANY and REUBEN B. OGENDO, *Kenya: A Study in Physical and Human Geography* (1973); D.C. EDWARDS and A.V. BOGDAN, *Important Grassland Plants of Kenya* (1951); and RICHARD S. ODINGO, *The Kenya Highlands: Land Use and Agricultural Development* (1971), analyze geographic and agricultural features. Population studies include S.H. OMINDE, ROUSHDI A. HENIN, and DAVID F. SLY (eds.), *Population and Development in Kenya* (1984), a useful focus on development implications of population growth; and S.H. OMINDE (ed.), *Kenya's Population Growth and Development to the Year 2000* (1988), an in-depth study. (S.H.O.)

BETHWELL A. OGOT (ed.), *Kenya Before 1900* (1976), contains essays on aspects of the history of various African peoples from about AD 500. ROBERT L. TIGNOR, *The Colonial Transformation of Kenya* (1976), recounts the impact of colonial rule on African individuals and societies from 1900 to 1939. MARJORIE RUTH DILLEY, *British Policy in Kenya Colony*, 2nd ed. (1966), explains the development of a British administrative philosophy to the mid-1930s. GUY ARNOLD, *Kenyatta and the Politics of Kenya* (1974), analyzes the role of Kenyatta in the political development of Kenya from 1922. DAVID THROUP, *Economic & Social Origins of Mau Mau, 1945–53* (1987), is well documented and researched. NORMAN N. MILLER, *Kenya: The Quest for Prosperity* (1984), carefully studies the politics, economics, and diplomacy of Kenya since independence. DONALD ROTHCHILD, *Racial Bargaining in Independent Kenya: A Study of Minorities and Decolonization* (1973), analyzes the conflict between ethnicity and national identity after independence. (K.In.)

Tanzania: Spatial aspects of resources and development are found in the official *Atlas of Tanzania*, 2nd ed. (1976); and the more comprehensive *Tanzania in Maps*, ed. by LEONARD BERRY (1971). ISSA G. SHIVJI, *Law, State, and the Working Class in Tanzania, c. 1920–1964* (1986), traces the creation of a working class during the colonial period. DEBORAH FAHY BRYCESON, *Food Insecurity and the Social Division of Labour in Tanzania, 1919–85* (1990), a thematic history of Tanzania, traces the development of the market, state, and client networks in relation to the fluctuation of the country's food supply. JANNIK BOESEN *et al.* (eds.), *Tanzania: Crisis and Struggle for Survival* (1986), collects articles on the rural economy written by a group of Scandinavian authors. ANDREW COULSON, *Tanzania: A Political Economy* (1982), is an interpretive account. (D.F.Br.)

I.N. KIMAMBO and A.J. TEMU (eds.), *A History of Tanzania* (1969), contains essays on political history from earliest times to independence. JOHN ILIFFE, *A Modern History of Tanganyika* (1979), is a comprehensive, documented, and scholarly general history from 1800 to 1961, mainly political but also economic and social, and *Tanganyika Under German Rule, 1905–1912* (1969), studies in detail the early colonial history. JOHN CHARLES HATCH, *Tanzania* (1972), by a sympathetic socialist writer, profiles the emergent country before and after independence. ANDREW ROBERTS (ed.), *Tanzania Before 1900* (1968), collects essays on the history of several ethnic groups before the colonial period. RODGER YEAGER, *Tanzania: An African Experiment*, 2nd ed., rev. and updated (1989), outlines the problems of independent Tanzania. JOHN GRAY, *History of Zanzibar, from the Middle Ages to 1856* (1962, reprinted 1975), offers a detached, scholarly study by a former chief justice of Zanzibar. ANTHONY CLAYTON, *The Zanzibar Revolution and Its Aftermath* (1981), gives a preliminary but acute assessment of the causes and immediate effects of the revolution of 1964. (K.In.)

Uganda: NELSON KASFIR, *The Shrinking Political Arena: Participation and Ethnicity in African Politics, with a Case Study of Uganda* (1976), examines ideas on ethnicity and ethnic categorizations in Uganda, drawing on case studies of ethnic

collision in the first Obote and Amin regimes. ALI A. MAZRUI, *Soldiers and Kinsmen in Uganda: The Making of a Military Ethnocracy* (1975), provides a fascinating if eclectic survey of modern Uganda, investigating the interplay between cultural, economic, and military forces. MICHAEL TWADDLE (ed.), *Expulsion of a Minority: Essays on Ugandan Asians* (1975), examines several aspects of Amin's summary expulsions of Asians. PETER LADEFOGED, RUTH GLICK, and CLIVE CRIPER, *Language in Uganda* (1972), is an interesting examination of the language scene. DUDLEY SEERS *et al.*, *The Rehabilitation of the Economy of Uganda*, 2 vol. (1979); and MARK BAIRD, *Uganda: Country Economic Memorandum* (1982), a World Bank study, detail economic development in independent Uganda. (O.H.K.)

SAMWIRI RUBARAZA KARUGIRE, *A Political History of Uganda* (1980), offers a brief, perceptive political history, mainly from 1860 to 1971. JAN JELMERT JØRGENSEN, *Uganda: A Modern History* (1981), is a scholarly account of the influence of the economy on Uganda's history from 1881 to 1979. T.V. SATHYAMURTHY, *The Political Development of Uganda, 1900–1986* (1986), details the history of colonial government and independence. M.S.M. SEMAKULA KIWANUKA, *A History of Buganda: From the Foundation of the Kingdom to 1900* (1971), chronicles the development of an African nation in a scholarly and well-researched manner. HOLGER BERNT HANSEN, *Mission, Church, and State in a Colonial Setting: Uganda, 1890–1925* (1984), carefully documents the important role played by Christian missionaries in the early years of British administration. MAHMOOD MAMDANI, *Politics and Class Formation in Uganda* (1976), gives a Marxist view of Uganda's history since the late 19th century. HOLGER BERNT HANSEN and MICHAEL TWADDLE (eds.), *Uganda Now: Between Decay and Development* (1988), collects essays on all aspects of Uganda's development since independence. (K.In.)

The countries of the Horn of Africa. *Djibouti:* Because most scholarship has been published in French, English-language sources for the geography and history of Djibouti are few and scattered. Among the fairly accessible articles and monographs in English on politics and economics are SAID YUSUF ABDI, "Independence for the Afars and Issas: Complex Background, Uncertain Future," *Africa Today*, 24(1):61–67 (January/March 1977), a succinct discussion of regional and internal politics at the time of independence; PETER D. COATS, "Factors of Intermediacy in Nineteenth-Century Africa: The Case of the Issa of the Horn," in THOMAS LABAHN (ed.), *Proceedings of the Second International Congress of Somali Studies*, vol. 2 (1984), pp. 175–199, an excellent analysis of the impact of the Franco-Ethiopian railway on the traditional trading networks and economy of the Issa Somali; and NORMAN N. MILLER, "The Other Somalia," *Horn of Africa*, 5(3):3–19 (1982), focusing on unrecorded trade between Somalia and Djibouti.

VIRGINIA THOMPSON and RICHARD ADLOFF, *Djibouti and the Horn of Africa* (1968), is the standard English-language text on the history of Djibouti, although it is now dated and lacks detail and depth of analysis; it can be supplemented by ROBERT THOLOMIER (ROBERT SAINT VÉRAN), *Djibouti, Pawn of the Horn of Africa*, abridged ed. (1981; originally published in French, 1977), covering the French Territory of the Afars and Issas from 1967 to 1977. The following French sources are also recommended: CENTRE DES HAUTES ÉTUDES SUR L'AFRIQUE ET L'ASIE MODERNES, *France, Océan Indien, Mer Rouge: études* (1986), with an extensive background chapter on Djibouti; PHILIPPE OBERLÉ and PIERRE HUGOT, *Histoire de Djibouti: des origines à la République* (1985), the most comprehensive history of Djibouti published to date; and OLIVIER WEBER (ed.), *Corne de l'Afrique* (1987), with several articles devoted to history, culture, and contemporary Djibouti life and with discussions developing the regional context. (C.C.C.)

Eritrea: A concise survey of ethnic groups living in Eritrea at the close of World War II is found in S.F. NADEL, *Races and Tribes of Eritrea* (1944). TEKESTE NEGASH, *Italian Colonialism in Eritrea, 1882–1941* (1987), surveys Italian colonialism and its impact on the people of Eritrea. G.K.N. TREVASKIS, *Eritrea: A Colony in Transition, 1941–52* (1960, reprinted 1975), recounts the political struggle over the fate of Eritrea in this time period. An account that reflects the Ethiopian point of view is HAGGAI ERLICH, *The Struggle Over Eritrea, 1962–1978* (1983). JOHN MARKAKIS, *National and Class Conflict in the Horn of Africa* (1987), includes an account of the Eritrean nationalist movement and the war of independence. JORDAN GEBRE-MEDHIN, *Peasants and Nationalism in Eritrea* (1989), analyzes Eritrean history from a nationalist perspective. (Jo.Ms.)

Ethiopia: EDWARD ULLENDORFF, *The Ethiopians: An Introduction to Country and People*, 3rd ed. (1973, reprinted 1990), is a comprehensive study; although some of the quantitative information is dated, the book makes interesting reading. MESFIN WOLDE-MARIAM, *An Introductory Geography of Ethiopia* (1972), is an excellent introduction providing information on the physical attributes, economic activities, population characteristics, and history of the country, and his *Rural Vulnerability to Famine in Ethiopia: 1958–1977* (1986), offers a valuable assessment, attempting to identify the human and natural causes of food insecurity. Two works on Ethiopia's peoples are those by Levine cited in the section above on the peoples of the Horn of Africa. DANIEL TEFERRA, *Social History and Theoretical Analyses of the Economy of Ethiopia* (1990), combines discussions on the historical geography of Ethiopia's people and on the current challenges in economic development. EDMOND J. KELLER, *Revolutionary Ethiopia: From Empire to People's Republic* (1988), deals with the political transformation of Ethiopia from its monarchist order to a people's republic. MULATU WUBNEH and YOHANNIS ABATE, *Ethiopia: Transition and Development in the Horn of Africa* (1988), is an excellent survey from a variety of perspectives, with discussions of the geography and history and of the country's social, cultural, political, and economic patterns. (A.Me.)

HAROLD G. MARCUS, *A History of Ethiopia* (1994), is the only modern general history of Ethiopia from *Australopithecus afarensis* to the fall of the Derg in 1991. Particular periods or events are covered in TADDESSE TAMRAT, *Church and State in Ethiopia, 1270–1527* (1972), which remains the only scholarly account of the golden years of the Solomonid dynasty; MOHAMMED HASSEN, *The Oromo of Ethiopia: A History, 1570–1860* (1990), the first modern history of the Oromo; MORDECHAI ABIR, *Ethiopia: The Era of the Princes: The Challenge of Islam and the Re-unification of the Christian Empire, 1769–1855* (1968), a dated but still largely accurate synthesis of the Age of the Princes; BAHRU ZEWDE, *A History of Modern Ethiopia, 1855–1974* (1991), a scholarly and authentically Ethiopian view; SVEN RUBENSON, *The Survival of Ethiopian Independence* (1976), an account that details the internal reasons for Ethiopia's continued independence during the epoch of modern European imperialism; CHRISTOPHER CLAPHAM, *Haile-Selassie's Government* (1969), an analysis of Haile Selassie's highly developed monarchical and authoritarian state; and JOHN W. HARBESON, *The Ethiopian Transformation: The Quest for the Post-Imperial State* (1988), a detailed account of the Mengistu years (1974–91) that argues against an Ethiopian revolution but for the notion of transformation. (H.G.M.)

Somalia: THOMAS LABAHN (ed.), *Proceedings of the Second International Congress of Somali Studies*, 4 vol. (1984), is a good collection of articles on socioeconomic development, politics, national science, and the arts. *Economic Transformation in a Socialist Framework* (1977), a report compiled by the JASPA Employment Advisory Mission, analyzes the economic changes under the socialist Somali government in the 1970s. JÖRG JANZEN, "Economic Relations Between Somalia and Saudi Arabia: Livestock Exports, Labor Migration, and the Consequences for Somalia's Development," *Northeast African Studies*, 8(2–3):41–51 (1986), analyzes the close economic interrelationship showing Somalia's dependence upon the Saudis. Janzen's "The Somali Inshore Fishing Economy: Structure, Problems, Perspectives," in ANNARITA PUGLIELLI (ed.), *Proceedings of the Third International Congress of Somali Studies* (1988), pp. 551–561, evaluates an important but under-exploited natural resource. JAN M. HAAKONSEN, *Scientific Socialism and Self Reliance* (1984), provides a well-informed account of the fishing cooperatives established for drought-afflicted pastoral nomads. PETER CONZE and THOMAS LABAHN (eds.), *Somalia: Agriculture in the Winds of Change* (1986), contains articles on the modern changes in crop production, pastoralism, and the socioeconomic environment. M.P.O. BAUMANN, JÖRG JANZEN, and H.J. SCHWARTZ (eds.), *Pastoral Production in Central Somalia* (1993), an interdisciplinary selection of articles, gives a profound insight into the structure and problems of Somalia's pastoral production. GARTH MASSY, *Subsistence and Change: Lessons of Agropastoralism in Somalia* (1987), explores the interfluvial area. ABDI ISMAIL SAMATAR, *The State and Rural Transformation in Northern Somalia, 1884–1986* (1989), is an analysis of the changes in rural areas. (J.H.A.J)

LEE V. CASSANELLI, *The Shaping of Somali Society: Reconstructing the History of a Pastoral People, 1600–1900* (1986), focuses on the history and society of southern Somalia. DAVID D. LAITIN and SAID S. SAMATAR, *Somalia: Nation in Search of a State* (1987), contains a general account of Somalian history, especially since independence in 1960. I.M. LEWIS, *A Modern History of Somalia: Nation and State in the Horn of Africa*, rev., updated, and expanded ed. (1988), is a comprehensive treatment of the political history of affairs in all the Somali territories. SAID S. SAMATAR, *Oral Poetry and Somali Nationalism* (1982), explains the crucial role of poetry in Somali politics, especially the case of nationalist leader Sayyid Maxamed Cabdulle Xasan, and his *Somalia: A Nation in Turmoil* (1991), provides a valuable overview of the factors leading to the collapse of the socialist state into clan-based warfare. AHMED I. SAMATAR, *Socialist Somalia: Rhetoric and Reality* (1988), analyzes the Siyaad regime's socialist policy of self-reliance and its efforts to achieve development. (I.M.L.)

Eastern Orthodoxy

Eastern Orthodoxy, characterized by its continuity with the apostolic church, its liturgy, and its territorial churches, is one of the three major branches of Christianity.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 827, and the *Index*.

This article is divided into the following sections:

Nature and significance

Eastern Orthodoxy is the large body of Christians who follow the faith and practices that were defined by the first seven ecumenical councils. The word orthodox ("right believing") has traditionally been used, in the Greek-speaking Christian world, to designate communities, or individuals, who preserved the true faith (as defined by those councils), as opposed to those who were declared heretical. The official designation of the church in Eastern Orthodox liturgical or canonical texts is "the Orthodox Catholic Church." Because of the historical links of Eastern Orthodoxy with the Eastern Roman Empire and Byzantium (Constantinople), however, in English usage it is referred to as the "Eastern" or "Greek Orthodox" Church. These terms are sometimes misleading, especially when applied to Russian or Slavic churches and to the Orthodox communities in western Europe and America. It should also be noted that there are Monophysitic churches (holding that after Incarnation Jesus had only a divine, and not a human and divine, nature) that have adopted the term orthodox as part of their names.

THE CULTURAL CONTEXT

The Schism of 1054

The schism between the churches of the East and the West (1054) was the culmination of a gradual process of estrangement that began in the first centuries of the Christian Era and continued through the Middle Ages. Linguistic and cultural differences, as well as political events, contributed to the estrangement. From the 4th to the 11th century, Constantinople, the centre of Eastern Christianity, was also the capital of the Eastern Roman, or Byzantine, Empire, while Rome, after the barbarian invasions, fell under the influence of the Holy Roman Empire of the West, a political rival. In the West theology remained under the influence of St. Augustine of Hippo (354–430), while in the East doctrinal thought was shaped by the Greek Fathers. Theological differences could have been settled if the two areas had not simultaneously developed different concepts of church authority. The growth of Roman primacy, based on the concept of the apostolic origin of the Church of Rome, was incompatible with the Eastern idea that the importance of certain local churches—Rome, Alexandria, Antioch, and later, Constantinople—could be determined only by their numerical and political significance. For the East, the highest authority in settling doctrinal disputes was the ecumenical council.

At the time of the Schism of 1054 between Rome and Constantinople, the membership of the Eastern Orthodox Church was spread throughout the Middle East, the Balkans, and Russia, with its centre in Constantinople, which was also called "New Rome." The vicissitudes of history have greatly modified the internal structures of the Orthodox Church, but, even today, the bulk of its members live in the same geographic areas. Missionary expansion toward Asia and emigration toward the West, however, have helped to maintain the importance of Orthodoxy worldwide.

THE NORM OF CHURCH ORGANIZATION

Autocephalous and autonomous churches

The Orthodox Church is a fellowship of "autocephalous" churches (governed by their own head bishops), with the Ecumenical Patriarch of Constantinople holding titular or honorary primacy. The number of autocephalous churches has varied in history. Today there are many: the Church of Constantinople (Istanbul), the Church of Alexandria (Egypt), the Church of Antioch (with headquarters in Damascus, Syria), and the churches of Jerusalem, Russia, Ukraine, Georgia, Serbia, Romania, Bulgaria, Cyprus, Greece, Albania, Poland, the Czech and Slovak republics, and America.

There are also "autonomous" churches (retaining a token canonical dependence upon a mother see) in Crete, Finland, and Japan. The first nine autocephalous churches are headed by "patriarchs," the others by archbishops or metropolitans. These titles are strictly honorary.

The order of precedence in which the autocephalous churches are listed does not reflect their actual influence or numerical importance. The patriarchates of Constantinople, Alexandria, and Antioch, for example, present only shadows of their past glory. Yet there remains a consensus that Constantinople's primacy of honour, recognized by the ancient canons because it was the capital of the ancient empire, should remain as a symbol and tool of church unity and cooperation. The modern pan-Orthodox conferences were thus convoked by the ecumenical patriarch of Constantinople. Several of the autocephalous churches are de facto national churches, by far the largest being the Russian Church; however, it is not the criterion of nationality but rather the territorial principle that is the norm of organization in the Orthodox Church.

Since the Russian Revolution there has been much turmoil and administrative conflict within the Orthodox Church. In western Europe and in the Americas, in particular, overlapping jurisdictions have been set up and political passions have led to the formation of ecclesiastical organizations without clear canonical status. Though it has provoked controversy, the establishment (1970) of the new autocephalous Orthodox Church in America by the patriarch of Moscow has as its stated goal the resumption of normal territorial unity in the Western Hemisphere.

History

THE CHURCH OF IMPERIAL BYZANTIUM

Byzantine Christianity about AD 1000. At the beginning of the 2nd millennium of Christian history, the church of Constantinople, capital of the Eastern Roman (or Byzantine) Empire, was at the peak of its world influence and power. Neither Rome, which had become a provincial town and its church an instrument in the hands of political interests, nor Europe under the Carolingian and Ottonian dynasties could really compete with Byzantium as centres of Christian civilization. The Byzantine emperors of the Macedonian dynasty had extended the frontiers of the empire from Mesopotamia to Naples (in Italy) and from the Danube River (in central Europe) to Palestine. The church of Constantinople not only enjoyed a parallel expansion but also extended its missionary penetration, much beyond the political frontiers of the empire, to Russia and the Caucasus.

Expansion of Byzantine church and state

Relations between church and state. The ideology that had prevailed since Constantine (4th century) and Justinian I (6th century)—according to which there was to be only one universal Christian society, the *oikoumenē*, led jointly by the empire and the church—was still the ideology of the Byzantine emperors. The authority of the patriarch of Constantinople was motivated in a formal fashion by the fact that he was the bishop of the "New Rome," where the emperor and the senate also resided (canon 28 of the Council of Chalcedon, 451). He held the title of "ecumenical patriarch," which pointed to his political role in the empire. Technically, he occupied the second rank—after the bishop of Rome—in a hierarchy of five major primates, which included also the patriarchs of Alexandria, Antioch, and Jerusalem. In practice, however, the latter three were deprived of all authority by the Arab conquest of the Middle East in the 7th century, and only the emerging Slavic churches attempted to challenge, at times, the position of Constantinople as the unique centre of Eastern Christendom.

The relations between state and church in Byzantium are often described by the term caesaropapism, which implies that the emperor was acting as the head of the church. The official texts, however, describe the emperor and the patriarch as a dyarchy (government with dual authority) and compare their functions to that of the soul and the body in a single organism. In practice, the emperor had the upper hand over much of church administration, though strong patriarchs could occasionally play a decisive role in politics: Patriarch Nicholas Mystikus (patriarch 901–907, 912–925) and Polyeuctus (patriarch 956–970) excommunicated emperors for uncanonical acts. In the area of faith and doctrine, the emperors could never impose their will when it contradicted the conscience of the church: this fact, shown in particular during the numerous attempts at union with Rome during the late medieval period, proves that the notion of caesaropapism is not unreservedly applicable to Byzantium.

Significance of Hagia Sophia

The Church of the Holy Wisdom, or Hagia Sophia, built by Justinian in the 6th century, was the centre of religious life in the Eastern Orthodox world. It was by far the largest and most splendid religious edifice in all of Christendom. According to *The Russian Primary Chronicle*, the envoys of the Kievan prince Vladimir, who visited it in 987, reported: "We knew not whether we were in heaven or on earth, for surely there is no such splendor or beauty anywhere upon earth." Hagia Sophia, or the "great church," as it was also called, provided the pattern of the liturgical office, which was adopted throughout the Orthodox world. This adoption was generally spontaneous, and it was based upon the moral and cultural prestige of the imperial capital: the Orthodox Church uses the 9th-century Byzantine Rite.

Monastic and mission movements. Both in the capital and in other centres, the monastic movement continued to flourish as it was shaped during the early centuries of Christianity. The Constantinopolitan monastery of Studion was a community of over 1,000 monks, dedicated to liturgical prayer, obedience, and asceticism. They frequently

The extent of Eastern Orthodoxy in the Balkans, the Middle East, eastern Europe, northern Asia, and Alaska.

opposed both government and ecclesiastical officialdom, defending fundamental Christian principles against political compromises. The Studite Rule (guidelines of monastic life) was adopted by daughter monasteries, particularly the famous Monastery of the Caves (Pecherskaya Lavra) in Kiev (in Russia). In 963 Emperor Nicephorus II Phocas offered his protection to St. Athanasius the Athonite, whose laura (large monastery) is still the centre of the monastic republic of Mt. Athos (under the protection of Greece). The writings of St. Symeon the New Theologian (949–1022), abbot of the monastery of St. Mamas in Constantinople, are a most remarkable example of Eastern Christian mysticism, and they exercised a decisive influence on later developments of Orthodox spirituality.

Missionary expansion

Historically, the most significant event was the missionary expansion of Byzantine Christianity throughout eastern Europe. In the 9th century, Bulgaria had become an Orthodox nation and under Tsar Symeon (893–927) had established its own autocephalous (administratively independent) patriarchate in Preslav. Under Tsar Samuel (976–1014) another autocephalous Bulgarian centre appeared in Ohrid. Thus, a Slavic-speaking daughter church of Byzantium dominated the Balkan Peninsula. It lost its political and ecclesiastical independence after the conquests of the Byzantine emperor Basil II (976–1025), but the seed of a Slavic Orthodoxy had been solidly planted. In 988 the Kievan prince Vladimir embraced Byzantine Orthodoxy and married a sister of Emperor Basil. After that time, Russia became an ecclesiastical province of the church of Byzantium, headed by a Greek or, less frequently, a Russian metropolitan appointed from Constantinople. This statute of dependence was not challenged by the Russians until 1448. During the entire period, Russia adopted and developed the spiritual, artistic, and social heritage of Byzantine civilization, which was received through intermediary Bulgarian translators. (See also below under *The church and the world—Missions: ancient and modern*).

Relations with the West. Relations with the Latin West, meanwhile, were becoming more ambiguous. On the one hand, the Byzantines considered the entire Western world as a part of the Roman *oikoumenē* of which the Byzantine emperor was the head and in which the Roman bishop enjoyed honorary primacy. On the other hand, the Frankish and German emperors in Europe were challenging this nominal scheme, and the internal decadence of the Roman papacy was such that the powerful patriarch of Byzantium seldom took the trouble of entertaining any relations with it. From the time of Patriarch Photius (patriarch 858–867, 877–886), the Byzantines had formally condemned the *Filioque* clause, which stated that the Holy Spirit proceeded from the Father and from the Son, as an illegitimate and heretical addition to the Nicene Creed, but in 879–880 Photius and Pope John VIII had apparently settled the matter to Photius' satisfaction. In 1014, however, the *Filioque* was introduced in Rome, and communion was broken again.

The background of the Schism of 1054

The incident of 1054, wrongly considered as the date of the Schism (which had actually been developing over a period of time), was, in fact, an unsuccessful attempt at restoring relations, disintegrating as they were because of political competition in Italy between the Byzantines and the Germans and also because of disciplinary changes (enforced celibacy of the clergy, in particular) imposed by the reform movement that had been initiated by the monks of Cluny, France. Conciliatory efforts of Emperor Constantine Monomachus (reigned 1042–55) were powerless to overcome either the aggressive and uninformed attitudes of the Frankish clergy, who were now governing the Roman Church, or the intransigence of Byzantine patriarch Michael Cerularius (1043–58). When papal legates came to Constantinople in 1054, they found no common language with the patriarch. Both sides exchanged recriminations on points of doctrine and ritual and finally hurled anathemas of excommunication at each other, thus provoking what has been called the Schism.

Invasions from East and West. *The Crusades.* After the Battle of Manzikert (1071) in eastern Asia Minor, Byzantium lost most of Anatolia to the Turks and ceased to be a world power. Partly solicited by the Byzantines, the Western Crusades proved another disaster: they brought the establishment of Latin principalities on former imperial territories and the replacement of Eastern bishops by a Latin hierarchy. The culminating point was, of course, the sack of Constantinople itself in 1204, the enthronement of a Latin emperor on the Bosporus, and the installation of a Latin patriarch in Hagia Sophia. Meanwhile, the Balkan countries of Bulgaria and Serbia secured national emancipation with Western help, the Mongols sacked Kiev (1240), and Russia became a part of the Mongol Empire of Genghis Khan.

The Byzantine heritage survived this series of tragedies mainly because the Orthodox Church showed an astonishing internal strength and a remarkable administrative flexibility.

Until the Crusades, and in spite of such incidents as the exchanges of anathemas between Michael Cerularius and the papal legates in 1054, Byzantine Christians did not consider the break with the West as a final schism. The prevailing opinion was that the break of communion with the West was due to a temporary take-over of the venerable Roman see by misinformed and uneducated German "barbarians," and that eventually the former unity of the Christian world under the one legitimate emperor—that of Constantinople—and the five patriarchates would be restored. This utopian scheme came to an end when the Crusaders replaced the Greek patriarchs of Antioch and Jerusalem with Latin prelates, after they had captured these ancient cities (1098–99). Instead of reestablishing Christian unity in the common struggle against Islām, the Crusades demonstrated how far apart Latins and Greeks really were from each other. When finally, in 1204, after a shameless sacking of the city, the Venetian Thomas Morosini was installed as patriarch of Constantinople and confirmed as such by Pope Innocent III, the Greeks realized the full seriousness of papal claims over the universal church: theological polemics and national hatreds were combined to tear the two churches further apart.

The sack of Constantinople and its aftermath

After the capture of the city, the Orthodox patriarch John Camaterus fled to Bulgaria and died there in 1206. A successor, Michael Autorianus, was elected in Nicaea (1208), where he enjoyed the support of a restored Greek empire. Although he lived in exile, this patriarch was recognized as legitimate by the entire Orthodox world. He continued to administer the immense Russian metropolitanate. From him, and not from his Latin competitor, the Bulgarian Church received again its right for ecclesiastical independence with a restored patriarchate in Trnovo (1235). It was also with the Byzantine government at Nicaea that the Orthodox Serbs negotiated the establishment of their own national church; their spiritual leader, St. Sava, was installed as autocephalous archbishop of Serbia in 1219.

The Mongol invasion. The invasion of Russia by the Mongols had disastrous effects on the future of Russian civilization, but the church survived, both as the only unified social organization and as the main bearer of the Byzantine heritage. The "metropolitan of Kiev and all Russia," who was appointed from Nicaea or from Constantinople, was a major political power, respected by the Mongol Khans. Exempt from taxes paid by the local princes to the Mongols and reporting only to his superior (the ecumenical patriarch), the head of the Russian Church—though he had to abandon his cathedral see of Kiev that had been devastated by the Mongols—acquired an unprecedented moral prestige. He retained ecclesiastical control over immense territories from the Carpathian Mountains to the Volga River, over the newly created episcopal see of Sarai (near the Caspian Sea), which was the capital of the Mongols, as well as over the Western principalities of the former Kievan Empire—even after they succeeded in winning independence (*e.g.*, Galicia) or fell under the political control of Lithuania and Poland.

Attempts at ecclesiastical union and theological renaissance. In 1261 the Nicaean emperor Michael Palaeologus recaptured Constantinople from the Latins, and an Orthodox patriarch again occupied the see in Hagia Sophia. From 1261 to 1453 the Palaeologan dynasty presided over an empire that was embattled from every side, torn apart by civil wars, and gradually shrinking to the very limits

Extension of ecclesiastical jurisdiction

of the imperial city itself. The church, meanwhile, kept much of its former prestige, exercising jurisdiction over a much greater territory, which included Russia as well as the distant Caucasus, parts of the Balkans, and the vast regions occupied by the Turks. Several patriarchs of this late period—*e.g.*, Arsenius Autorianus (patriarch 1255–59, 1261–65), Athanasius I (patriarch 1289–93, 1303–10), John Calecas (patriarch 1334–47), and Philotheus Coccinus (patriarch 1353–54, 1364–76)—showed great independence from the imperial power, though remaining faithful to the ideal of the Byzantine *oikoumenē*.

Without the military backing of a strong empire, the patriarchate of Constantinople was, of course, unable to assert its jurisdiction over the churches of Bulgaria and Serbia, which had gained independence during the days of the Latin occupation. In 1346 the Serbian Church even proclaimed itself a patriarchate; a short-lived protest by Constantinople ended with recognition in 1375. In Russia, Byzantine ecclesiastical diplomacy was involved in a violent civil strife; a fierce competition arose between the grand princes of Moscow and Lithuania, who both aspired to become leaders of a Russian state liberated from the Mongol yoke. The "metropolitan of Kiev and all Russia" was by now residing in Moscow, and often, as in the case of the metropolitan Alexis (1354–78), played a directing role in the Muscovite government. The ecclesiastical support of Moscow by the church was decisive in the final victory of the Muscovites and had a pronounced impact on later Russian history. The dissatisfied western Russian principalities (which would later constitute the Ukraine) could only obtain—with the strong support of their Polish and Lithuanian overlords—the temporary appointment of separate metropolitans in Galicia and Belorussia. Eventually, late in the 14th century, the metropolitan residing in Moscow again centralized ecclesiastical power in Russia.

Relations with the Western Church. One of the major reasons behind this power struggle in the northern area of the Byzantine world was the problem of relations with the Western Church. To most Byzantine churchmen, the young Muscovite principality appeared to be a safer bulwark of Orthodoxy than the Western-oriented princes who had submitted to Catholic Poland and Lithuania. Also, an important political party in Byzantium itself favoured union with the West in the hope that a new Western Crusade might be made against the menacing Turks. The problem of ecclesiastical union was, in fact, the most burning issue during the entire Palaeologan period.

The problem of ecclesiastical union

Emperor Michael Palaeologus (1259–82) had to face the aggressive ambition of the Sicilian Norman king Charles of Anjou, who dreamed of restoring the Latin empire in Constantinople. To gain the valuable support of the papacy against Charles, Michael sent a Latin-inspired confession of faith to Pope Gregory X, and his delegates accepted union with Rome at the Council of Lyons (1274). This capitulation before the West, sponsored by the Emperor, won little support in the church. During his lifetime, Michael succeeded in imposing an Eastern Catholic patriarch, John Beccus, upon the Church of Constantinople, but upon Michael's death an Orthodox council condemned the union (1285).

Throughout the 14th century, numerous other attempts at negotiating union were initiated by the emperors of Byzantium. Formal meetings were held in 1333, 1339, 1347, and 1355. In 1369 Emperor John V Palaeologus was personally converted to the Roman faith in Rome. All these attempts were initiated by the government and not by the church, for an obvious political reason; *i.e.*, the hope for Western help against the Turks. But the attempts brought no results either on the ecclesiastical or on the political levels. The majority of Byzantine Orthodox churchmen were not opposed to the idea of union but considered that it could only be brought about through a formal ecumenical council at which East and West would meet on equal footing, as they had done in the early centuries of the church. The project of a council was promoted with particular consistency by John Cantacuzenus, who, after a brief reign as emperor (1347–54), became a monk but continued to exercise great influence on all ecclesiastical and political events. The idea of an ecumenical council was initially rejected by the popes, but it was revived in the 15th century with the temporary triumph of conciliarist ideas (which advocated more power to councils and less to popes) in the West at the councils of Constance and Basel. Challenged with the possibility that the Greeks would unite with the conciliarists and not with Rome, Pope Eugenius IV called an ecumenical council of union in Ferrara, which later moved to Florence.

The Council of Ferrara–Florence

The Council of Ferrara–Florence (1438–45) lasted for months and allowed for long theological debates. Emperor John VIII Palaeologus, Patriarch Joseph, and numerous bishops and theologians represented the Eastern Church. They finally accepted most Roman positions—the *Filioque* clause, purgatory (an intermediate stage for the soul's purification between death and heaven), and the Roman primacy. Political desperation and the fear of facing the Turks again, without Western support, was the decisive factor that caused them to place their signatures of approval on the Decree of Union (July 6, 1439). The metropolitan of Ephesus, Mark Eugenicus, alone refused to sign. Upon their return to Constantinople, most other delegates also renounced their acceptance of the council and no significant change occurred in the relations between the churches.

The official proclamation of the union in Hagia Sophia was postponed until December 12, 1452; however, on May 29, 1453, Constantinople fell to the Ottoman Turks. Sultan Mehmed II transformed Hagia Sophia into an Islāmic mosque, and the few partisans of the union fled to Italy.

Theological and monastic renaissance. Paradoxically, the pitiful history of Byzantium under the Palaeologan emperors coincided with an astonishing intellectual, spiritual, and artistic renaissance that influenced the entire Eastern Christian world. The renaissance was not without fierce controversy and polarization. In 1337 Barlaam the Calabrian, one of the representatives of Byzantine Humanism, attacked the spiritual practices of the Hesychast (from the Greek word *hēsychia*, meaning quiet) monks, who claimed that Christian asceticism and spirituality could lead to the vision of the "uncreated light" of God. Barlaam's position was upheld by several other theologians, including Akyndinus and Nicephorus Gregoras. After much debate, the

Pierre Vals—*Paris Match*

Orthodox monk meditating in a chapel on Mount Athos

church gave its support to the main spokesman of the monks, Gregory Palamas (1296–1359), who showed himself as one of the foremost theologians of medieval Byzantium. The councils of 1341, 1347, and 1351 adopted the theology of Palamas, and, after 1347, the patriarchal throne was consistently occupied by his disciples. John VI Cantacuzenus, who, as emperor, presided over the council of 1351, gave his full support to the Hesychasts. His close friend, Nicholas Cabasilas, in his spiritual writings on the divine liturgy and the sacraments, defined the universal Christian significance of Palamite theology. The influence of the religious zealots, who triumphed in Constantinople, outlasted the empire itself and contributed to the perpetuation of Orthodox spirituality under the Turkish rule. It also spread to the Slavic countries, especially Bulgaria and Russia. The monastic revival in northern Russia during the last half of the 14th century, which was associated with the name of St. Sergius of Radonezh, as well as the contemporaneous revival of iconography (*e.g.,* the work of the great painter Andrey Rublyov), would have been unthinkable without constant contacts with Mt. Athos, the centre of Hesychasm, and with the spiritual and intellectual life of Byzantium.

Along with the Hesychast revival, a significant "opening to the West" was taking place among some Byzantine ecclesiastics. The brothers Prochorus and Demetrius Cydones, under the sponsorship of Cantacuzenus, for example, were systematically translating the works of Latin theologians into Greek. Thus, major writings of Augustine, Anselm of Canterbury, and Thomas Aquinas were made accessible to the East for the first time. Most of the Latin-minded Greek theologians eventually supported the union policy of the emperors, but there were some—like Gennadios II Scholarios, the first patriarch under the Turkish occupation—who reconciled their love for Western thought with total faithfulness to the Orthodox Church.

ORTHODOXY UNDER THE OTTOMANS (1453–1821)

The Christian ghetto. According to Muslim belief, Christians, as well as Jews, were considered as "people of the Book"; *i.e.,* their religion was seen as not entirely false, but incomplete. Accordingly, provided that Christians submitted to the dominion of the caliphate and the Muslim political administration and paid appropriate taxes, they deserved consideration and freedom of worship. Any Christian mission or proselytism among the Muslims, however, was considered a capital crime. In fact, Christians were formally reduced to a ghetto existence: they were the *Rūm millet,* or the "Roman nation" conquered by Islām but enjoying a certain internal autonomy.

Conditions of Christians under Muslim rule

In January 1454 the Sultan allowed the election of a new patriarch, who was to become *millet-bachi,* the head of the entire Christian *millet,* or in Greek the "ethnarch," with the right to administer, to tax, and to exercise justice over all the Christians of the Turkish empire. Thus, under the new system, the patriarch of Constantinople saw his formal rights and jurisdiction extended both geographically and substantially: on the one hand, through the privileges granted to him by the sultan, he could practically ignore his colleagues, the other Orthodox patriarchs, and, on the other hand, his power ceased to be purely canonical and spiritual but became political as well. To the enslaved Greeks, he appeared not only as the successor of the Byzantine patriarchs but also as the heir of the emperors. For the Ottomans, he was the official and strictly controlled administrator of the *Rūm millet.* In order to symbolize these new powers, the patriarch adopted an external attire reminiscent of that of the emperors: mitre in form of a crown, long hair, eagles as insignia of authority, and other imperial accoutrements.

Consequences of the *millet* system

The new system had many significant consequences. Most important, it permitted the church to survive as an institution; indeed, the prestige of the church was actually increased because, for Christians, the church was now the only source of education and it alone offered possibilities of social promotion. Moreover, through the legal restrictions placed on mission, the new arrangement created the practical identification of church membership with ethnic origin. And finally, since the entire Christian *millet* was ruled by the patriarch of Constantinople and his Greek staff, it guaranteed to the Phanariots, the Greek aristocracy of the Phanar (now called Fener, the area of Istanbul where the patriarchate was, and still is, located), a monopoly in episcopal elections. Thus, Greek bishops progressively came to occupy all the hierarchical positions. The ancient patriarchates of the Middle East were practically governed by the Phanar. The Serbian and Bulgarian churches came to the same fate: the last remnants of their autonomy were formally suppressed in 1766 and 1767, respectively, by the Phanariot patriarch Samuel Hantcherli. This Greek control, exercised through the support of the hated Turks, was resented more and more by the Balkan Slavs and Romanians as the Turkish regime became more despotic, taxes grew heavier, and modern nationalisms began to develop.

It is necessary, however, to credit the Phanariots with a quite genuine devotion to the cause of learning and education, which they alone were able to provide inside the oppressed Christian ghetto. The advantages they obtained from the Porte (the Turkish government) for building schools and for developing Greek letters in the Romanian principalities of Moldavia and Walachia that were entrusted to their rule came to play a substantial role in the rebirth of Greece.

Relations with the West. The Union of Florence became fully inoperative as soon as the Turks occupied Constantinople (1453). In 1484 a council of bishops condemned it officially. Neither the sultan nor the majority of the Orthodox Greeks were favourable to the continuation of political ties with Western Christendom. The Byzantine cultural revival of the Palaeologan period was the first to experience adverse effects from the occupation. Intellectual dialogue with the West became impossible. Through liturgical worship and the traditional spirituality of the monasteries, the Orthodox faith was preserved in the former Byzantine world. Some self-educated men developed a remarkable ability to develop the Orthodox tradition through writings and publications, but they were isolated exceptions. Probably the most remarkable among them was St. Nicodemus of the Holy Mountain, the Hagiorite (1748–1809), who edited the famous *Philocalia,* an anthology of spiritual writings, and also translated and adapted Western spiritual writings (*e.g.,* those of the Jesuit founder, Ignatius of Loyola) into modern Greek.

East–West contacts

The only way for Orthodox Greeks, Slavs, or Romanians to acquire an education higher than the elementary level was to go to the West. Several of them were able to do so, but, in the process, became detached from their own theological and spiritual tradition.

The West, in spite of much ignorance and prejudice, had a constant interest in the Eastern Church. At times there was a genuine and respectful curiosity; in other instances, political and proselytistic (conversion) concerns prevailed. Thus, in 1573–81, a lengthy correspondence was initiated by the Lutheran scholars from Tübingen (in Germany). However interesting as a historical event, this correspondence, which includes the *Answers* of Patriarch Jeremias II (patriarch 1572–95), shows how little mutual understanding was possible at that time between the Reformers and traditional Eastern Christianity.

Relations with the West, especially after the 17th century, were often vitiated in the East by the incredible corruption of the Turkish government, which constantly fostered diplomatic intrigues. An outstanding example of such manipulation was the *kharāj,* an important tax required by the Porte at each patriarchal election. Western diplomats were often ready to provide the amount needed in order to secure the election of candidates favourable to their causes. The French and Austrian ambassadors, for example, supported candidates who would favour the establishment of Roman Catholic influence in the Christian ghetto, while the British and Dutch envoys supported patriarchs who were open to Protestant ideas. Thus, a gifted and Western-educated patriarch, Cyril Lucaris, was elected and deposed five times between 1620 and 1638. His stormy reign was marked by the publication in Geneva of a *Confession of Faith* (1629), which was, to the great amazement of all contemporaries, purely Calvinistic (*i.e.,* it contained Re-

formed Protestant views). The episode ended in tragedy. Cyril was strangled by Turkish soldiers at the instigation of the pro-French and pro-Austrian party. Six successive Orthodox councils condemned the *Confession:* Constantinople, 1638; Kiev, 1640; Jassy, 1642; Constantinople, 1672; Jerusalem, 1672; and Constantinople, 1691. In order to refute its positions, the metropolitan of Kiev, Peter Mogila, published his own *Orthodox Confession of Faith* (1640), which was followed, in 1672, by the *Confession* of the patriarch of Jerusalem, Dositheos Notaras. Both, especially Peter Mogila, were under strong Latin influence.

These episodes were followed, in the 18th century, by a strong anti-Western reaction. In 1755 the Synod of Constantinople decreed that all Westerners—Latin or Protestant—had invalid sacraments and were only to be admitted into the Orthodox Church through Baptism. This practice of the Greek Church fell into disuse only in the 20th century.

THE CHURCH OF RUSSIA (1448–1800)

The "third Rome." *Origin of the Muscovite patriarchate.* At the Council of Florence, the Greek "metropolitan of Kiev and all Russia," Isidore, was one of the major architects of the Union. Having signed the decree, he returned to Moscow in 1441 as a Roman cardinal but was rejected by both church and state, arrested, and then allowed to escape to Lithuania. In 1448, after much hesitation, the Russians received a new primate, Jonas, elected by their own bishops. Their church became autocephalous, administratively independent under a "metropolitan of all Russia," residing in Moscow. In territories controlled by Poland, Rome (in 1458) appointed another "metropolitan of Kiev and all Russia." The tendencies toward separation from Moscow that had existed in the Ukraine since the Mongol invasion and that were supported by the kings of Poland thus received official sanction. In 1470, however, this metropolitan broke the union with the Latins and reentered—nominally—the jurisdiction of Constantinople, by then under Turkish control.

Independence of the Moscow metropolitanate

After this, the fate of the two churches "of all Russia" became quite distinct. The metropolitanate of Kiev developed under the control of Roman Catholic Poland. Hard pressed by the Polish kings, the majority of its bishops, against the will of the majority of their flock, eventually accepted union with Rome at Brest-Litovsk (1596). In 1620, however, an Orthodox hierarchy was reestablished, and a Romanian nobleman, Peter Mogila, was elected metropolitan of Kiev (1632). He created the first Orthodox theological school of the modern period, the famous Academy of Kiev. Modelled after the Latin seminaries of Poland, with instruction given in Latin, this school served as the theological training centre for almost the entire Russian high clergy in the 17th and 18th centuries. In 1686 the Ukraine was finally reunited with Muscovy, and the metropolitanate of Kiev was attached to the patriarchate of Moscow, with approval given by Constantinople.

Muscovite Russia, meanwhile, had acquired the consciousness of being the last bulwark of true Orthodoxy. In 1472 Grand Prince Ivan III (reigned 1462–1505) married Sofia (Zoë), the niece of the last Byzantine emperor. The Muscovite sovereign began to use more and more of the Byzantine imperial ceremonial, and he assumed the double-headed eagle as his state emblem. In 1510 the monk Philotheus of Pskov addressed Vasily III as "tsar" (or emperor), saying: "Two Romes have fallen, but the third stands, and a fourth there will not be." The meaning of the sentence was that the first Rome was heretical, the second—Byzantium—was under Turkish control, and the third was Moscow. Ivan IV, the Terrible, was crowned emperor, according to the Byzantine ceremonial, by the metropolitan of Moscow, Makary, on January 16, 1547. In 1551 he solemnly presided in Moscow over a great council of Russian bishops, the Stoglav ("Council of 100 Chapters"), in which various issues of discipline and liturgy were settled and numerous Russian saints were canonized. These obvious efforts to live up to the title of the "third Rome" lacked one final sanction: the head of the Russian Church was lacking the title of "patriarch." The "tsars" of Bulgaria and Serbia did not hesitate in the past to bestow the title on their own primates, but the Russians wanted an unquestionable authentication and waited for proper opportunity. It occurred in 1589 when the patriarch of Constantinople, Jeremias II, was on a fund-raising tour of Russia. He could not resist the pressure of his hosts and established the metropolitan Job as "patriarch of Moscow and all Russia." Confirmed later by the other Eastern patriarchs, the new patriarchate obtained the fifth place in the honorific order of the Oriental sees, after the patriarchs of Constantinople, Alexandria, Antioch, and Jerusalem.

The "third Rome" ideology

Relations between patriarch and tsar. After the 16th century, the Russian tsars always considered themselves as successors of the Byzantine emperors and the political protectors and financial supporters of Orthodoxy throughout the Balkans and the Middle East. The patriarch of Moscow, however, never pretended to occupy formally the first place among the patriarchs. Within the Muscovite Empire, many traditions of medieval Byzantium were faithfully kept. A flourishing monastic movement spread the practice of Christian asceticism in the northern forests, which were both colonized and Christianized by the monks. St. Sergius of Radonezh (*c.* 1314–92) was the spiritual father of this monastic revival. His contemporary, St. Stephen of Perm, missionary to the Zyryan tribes, continued the tradition of SS. Cyril and Methodius, the "apostles to the Slavs" in the 9th century, in translating the Scripture and the liturgy into the vernacular. He was followed by numerous other missionaries who promoted Orthodox Christianity throughout Asia and even established themselves on Kodiak Island off the coast of Alaska (1794). The development of church architecture, iconography, and literature also added to the prestige of the "third Rome."

Russian monastic and missionary activities

The Muscovite Empire, however, was quite different from Byzantium both in its political system and in its cultural self-understanding. The Byzantine "symphony" (harmonious relationship) between the emperor and the patriarch was never really applied in Russia. The secular goals of the Muscovite state and the will of the monarch always superseded canonical or religious considerations, which were still binding on the medieval emperors of Byzantium. Muscovite political ideology was always influenced more by the beginnings of western European secularism and by Asiatic despotism than by Roman or Byzantine law. Though strong patriarchs of Constantinople were generally able to oppose open violations of dogma and canon law by the emperors, their Russian successors were quite powerless; a single metropolitan of Moscow, St. Philip (metropolitan 1566–68), who dared to condemn the excesses of Ivan IV, was deposed and murdered.

A crisis of the "third Rome" ideology occurred in the middle of the 17th century. Nikon (reigned 1652–58), a strong patriarch, decided to restore the power and prestige of the church by declaring that the patriarchal office was superior to that of the tsar. He forced the tsar Alexis Romanov to repent for the crime of his predecessor against St. Philip and to swear obedience to the church. Simultaneously, Nikon attempted to settle a perennial issue of Russian church life: the problem of the liturgical books. Originally translated from the Greek, the books suffered many corruptions through the centuries and contained numerous mistakes. In addition, the different historical developments in Russia and in the Middle East had led to differences between the liturgical practices of the Russians and the Greeks. Nikon's solution was to order the exact compliance of all the Russian practices with the contemporary Greek equivalents. His liturgical reform led to a major schism in the church. The Russian masses had taken seriously the idea that Moscow was the last refuge of Orthodoxy. They wondered why Russia had to accept the practices of the Greeks, who had betrayed Orthodoxy in Florence and had been justly punished by God, in their view, by becoming captives of the infidel Turks. The reformist decrees of the patriarch were rejected by millions of lower clergy and laity who constituted the Raskol, or schism of the "Old Believers." Nikon was ultimately deposed for his opposition to the tsar, but his liturgical reforms were confirmed by a great council of the church

Schism in the Russian Church

that met in the presence of two Eastern patriarchs (1666–67).

The reforms of Peter the Great (reigned 1682–1725). The son of Tsar Alexis, Peter the Great, changed the historical fate of Russia by radically turning away from the Byzantine heritage and reforming the state according to the model of Protestant Europe. Humiliated by his father's temporary submission to Patriarch Nikon, Peter prevented new patriarchal elections after the death of Patriarch Adrian in 1700. After a long vacancy of the see, he abolished the patriarchate altogether (1721) and transformed the central administration of the church into a department of the state, which adopted the title of "Holy Governing Synod." An imperial high commissioner (*Oberprokuror*) was to be present at all meetings and, in fact, to act as the administrator of church affairs. Peter also issued a lengthy *Spiritual Regulation* (*Dukhovny Reglament*) that served as bylaws for all religious activities in Russia. Weakened by the schism of the "Old Believers," the church found no spokesman to defend its rights and passively accepted the reforms.

With the actions of Peter, the Church of Russia entered a new period of its history that lasted until 1917. The immediate consequences were not all negative. Peter's ecclesiastical advisers were Ukrainian prelates, graduates of the Kievan academy, who introduced in Russia a Western system of theological education; the most famous among them was Peter's friend, Feofan Prokopovich, archbishop of Pskov. Throughout the 18th century, the Russian Church also continued its missionary work in Asia and produced several spiritual writers and saints: St. Mitrofan of Voronezh (died 1703), St. Tikhon of Zadonsk (died 1783)—an admirer of the German Lutheran Johann Arndt and of German Pietism—as well as other eminent prelates and scholars such as Platon Levshin, metropolitan of Moscow (died 1803). All attempts at challenging the power of the tsar over the church, however, always met with failure. The metropolitan of Rostov, Arseny Matsiyevich, who opposed the secularization of church property by the empress Catherine the Great, was deposed and died in prison (1772). The atmosphere of secularistic officialdom that prevailed in Russia was not favourable for a revival of monasticism, but such a revival did take place through the efforts of a young Kievan scholar, Paissy Velichkovsky (1722–94), who became the abbot of the monastery of Neamts in Romania. His Slavonic edition of the *Philocalia* contributed to the revival of Hesychast traditions in Russia in the 19th century.

THE ORTHODOX CHURCHES IN THE 19TH CENTURY

Autocephalies in the Balkans. The ideas of the French Revolution, the nationalistic movements, and the everliving memory of past Christian empires led to the gradual disintegration of Turkish domination in the Balkans. According to a pattern existing since the late Middle Ages, the birth of national states was followed by the establishment of independent, autocephalous Orthodox churches. Thus the collapse of the Ottoman rule was accompanied by the rapid shrinking of the actual power exercised by the patriarch of Constantinople. Paradoxically, the Greeks, for whom—more than anyone—the patriarchate represented a hope for the future, were the first to organize an independent church in their new state.

The establishment of independent nationalistic churches

In Greece. In 1821 the Greek revolution against the Turks was officially proclaimed by the metropolitan of Old Patras, Germanos. The patriarchate, being the official Turkish-sponsored organ for the administration of the Christians, issued statements condemning and even anathematizing the revolutionaries. These statements, however, failed to convince anyone, least of all the Turkish government, which on Easter Day in 1821 had the ecumenical (Constantinopolitan) patriarch Gregory V hanged from the main gate of the patriarchal residence as a public example. Numerous other Greek clergy were executed in the provinces. After this tragedy, the official loyalty of the patriarchate was, of course, doubly secured. Unable either to communicate with the patriarchate or to recognize its excommunications, the bishops of liberated Greece gathered in Návplion and established themselves as the synod of an autocephalous church (1833). The eclesiastical regime adopted in Greece was modelled after that of Russia: a collective state body, the Holy Synod, was to govern the church under strict government control. In 1850 the patriarchate was forced to recognize what was by then a fait accompli, and granted a charter of autocephaly (*tómos*) to the new Church of Greece.

In Serbia. The independence of Serbia led, in 1832, to the recognition of Serbian ecclesiastical autonomy. In 1879

the Serbian Church was recognized by Constantinople as autocephalous under the primacy of the metropolitan of Belgrade. This church, however, covered only the territory of what was called "old Serbia." The small state of Montenegro, always independent from the Turks, had its own metropolitan in Cetinje. This prelate, who was also the civil and military leader of the nation, was consecrated either in Austria, or, as in the case of the famous bishop-poet Pyotr II Negosh, in St. Petersburg (1833).

In the Austro-Hungarian empire, two autocephalous churches, with jurisdiction over Serbs, Romanians, and other Slavs, were in existence during the second half of the century. These were the patriarchate of Sremski-Karlovci (Karlowitz), established in 1848, which governed all the Orthodox in the Kingdom of Hungary; and the metropolitanate of Czernowitz (now Chernovtsy) in Bukovina, which, after 1873, also exercised jurisdiction over two Serbian dioceses (Zara and Kotor) in Dalmatia. The Serbian dioceses of Bosnia and Herzegovina, acquired by Austria in 1878, remained autonomous but were never completely independent from Constantinople.

In Romania. The creation of an independent Romania, after centuries of foreign control by Bulgarians, Turks, Greek-Phanariots, and, more recently, Russians, led in 1865 to the self-proclamation of the Romanian Church as autocephalous, even against the violent protests of the Phanar. As in Greece, the new church was under the strict control of the pro-Western government of Prince Alexandru Cuza. Finally, as in the Greek case, Constantinople recognized the Romanian autocephaly under the metropolitan of Bucharest (1885). The Romanians of Transylvania, still in Austria–Hungary, remained under the autocephalous metropolitan of Sibiu and others under the church of Czernowitz.

In Bulgaria. The reestablishment of the Church of Bulgaria eventually was secured, but not without tragedy and even a schism; this happened mainly because the issue of reestablishing the autocephalous church arose at a time when both Greek and Bulgarian populations lived side by side in Macedonia, Thrace, and Constantinople itself, though still within the framework of the Ottoman imperial system. After the Turkish conquest, and especially in the 17th and 18th centuries, the Bulgarians were governed by Greek bishops and were often prevented from worshipping in Slavonic. This enforced policy of Hellenization was rejected in the 19th century when Bulgarians began to claim not only a native clergy but also equal representation on the higher echelons of the Christian *millet—i.e.*, the offices of the patriarchate. These claims were met with firm resistance by the Greeks. The alternative was a national Bulgarian Church, which was created by a sultan's firman (decree) in 1870. The new church was to be governed by its own Bulgarian exarch, who resided in Constantinople itself and governed all the Bulgarians who recognized him. The new situation was uncanonical, because it sanctioned the existence of two separate ecclesiastical structures on the same territory. Ecumenical Patriarch Anthimus VI convened a synod in Constantinople, which also included the Greek patriarchs of Alexandria and Jerusalem (1872). The council condemned "phyletism"—the national or ethnic principle in church organization—and excommunicated the Bulgarians, who were certainly not alone guilty of "phyletism." This schism lasted until 1945, when a reconciliation took place with full recognition of Bulgarian autocephaly within the limits of the Bulgarian state.

The problem of the national or ethnic principle

After their liberation from the Turkish yoke, the Balkan churches freely developed both their national identities and their religious life. Theological faculties, generally following German models, were created in Athens, Belgrade (in Yugoslavia), Sofia (in Bulgaria), and Bucharest (in Romania). The Romanian Church introduced the full cycle of the liturgical offices in vernacular Romanian. But these positive developments were often marred by nationalistic rivalries. In condemning "phyletism," the synod of Constantinople (1872) had, in fact, defined a basic problem of modern Orthodoxy.

The church in imperial Russia. The *Spiritual Regulation* of Peter the Great remained in force until the very end of the Russian Empire (1917). Many Russian churchmen consistently complained against the submission of the church to the state, but there was little they could do except to lay plans for future reforms. This they did not fail to do, and in the 20th century the necessary changes were rapidly enacted. Though Peter himself and his first successors tended to deal personally and directly with church affairs, the tsars of the 19th century delegated much authority to the *Oberprokurors*, who received a cabinet rank in the government and were the real heads of the entire administration of the church. One of the most debilitating aspects of the regime was the legal division of Russian society by a rigid caste system. The clergy was one of the castes with its own school system, and there was little possibility for its children to choose another career.

In spite of these obvious defects, the church kept its self-awareness, and among the episcopate such eminent figures as Philaret of Moscow (1782–1867) promoted education, theological research, biblical translations, and missionary work. In each of its 67 dioceses, the Russian Church created a seminary for the training of priests and teachers. In addition, four theological academies, or graduate schools, were established in major cities (Moscow, 1769; St. Petersburg, 1809; Kiev, 1819; Kazan, 1842). They provided a generally excellent theological training for both Russians and foreigners. The rigid caste system and the strictly professional character of these schools, however, were obstacles to their seriously influencing society at large. It was, rather, through the monasteries and their spirituality that the church began to reach the intellectual class. More influential than the rigid discipline of the large monastic communities, the prophetic ministry of the "elders" (*startsy*), who acted as living examples of the standards of the spiritual life or as advisers and confessors, attracted large masses of the common people, and also intellectuals. St. Seraphim of Sarov (1759–1833), for example, lived according to the standards of the ancient Hesychast tradition that had been revived in the Russian forests. The *startsy* of Optino—Leonid (1768–1841), Makarius (1788–1860), and Ambrose (1812–91)—were visited not only by thousands of ordinary Christians but also by the writers Nikolay Gogol, Leo Tolstoy, and Fyodor Dostoyevsky. The latter was inspired by the *startsy* when he described in his novels monastic figures such as Zosima in *The Brothers Karamazov*. From the ranks of an emerging group of Orthodox lay intellectuals, the production of a living theology—if less scholarly than in the academies—was taking shape. The great influence of a lay theologian like Aleksey Khomyakov (1804–60), who belonged to the Slavophile (pro-Slavic) circle before it acquired a political flavour, eventually helped in the conversion to Orthodoxy at the end of the century of such leading Marxists as Sergey Bulgakov (1871–1944) and Nikolay Berdyayev (1874–1948). Missionary expansion also continued, particularly in western Asia, Japan, and Alaska (see below, *The church and the world: Missions: ancient and modern*).

Significance of Russian monasticism

Disproportionately larger and richer than its sister churches of the Balkans and the Middle East, the Church of Russia included, in 1914, more than 50,000 priests, 21,000 monks, and 73,000 nuns. It supported thousands of schools and missions. It cooperated with the Russian government in exercising great influence in Mid-Eastern affairs. Thus, with Russian help, an Arab (Meletios Doumani) rather than a Greek was elected for the first time as patriarch of Antioch (1899). With the successive partitions of Poland and the reunions with Russia of Belorussian and Ukrainian territories, many Eastern Catholic descendants of those who had joined the Roman communion in Brest-Litovsk (1596) returned to Orthodoxy.

The condition of the Russian Church on the eve of World War I

After 1905, Tsar Nicholas II gave his approval for the establishment of a preconciliar commission charged with the preparation of an all-Russian Church Council. The avowed goal of the planned assembly was to reestablish the church's independence, lost since Peter the Great, and eventually to restore the patriarchate. This assembly, however, was fated to meet only after the fall of the empire.

THE ORTHODOX CHURCH SINCE WORLD WAR I

The almost complete disappearance of Christianity in Asia Minor, the regrouping of the Orthodox churches in the

Balkans, the tragedy of the Russian Revolution, and the Orthodox diaspora in the West radically changed the entire structure of the Orthodox world.

The Russian Revolution and the Soviet period. The Church of Russia was less unprepared than generally believed to face the revolutionary turmoil. Projects of necessary reforms had been prepared since 1905, and most clergy did not feel particularly attached to the fallen regime that had deprived the church of its freedom for several centuries. During the rule of the provisional government, in August 1917 a council representing the entire church met in Moscow, including 265 members of the clergy and 299 laymen. The democratic composition and program of the council had been planned by the Pre-Conciliar Commission. It adopted a new constitution of the church that provided for the reestablishment of the patriarchate, the election of bishops by the dioceses, and the representation of laymen on all levels of church administration. It was only in the midst of the new revolutionary turmoil, however, that Tikhon, metropolitan of Moscow, was elected patriarch (October 31, 1917—six days after the Bolshevik takeover). The bloody events into which the country was plunged did not allow all the reforms to be carried out, but the people elected new bishops in several dioceses.

The effects of the Russian Revolution on the church

The Bolshevik government, because of its Marxist ideology, considered all religion as the "opium of the people." On January 20, 1918, it published a decree depriving the church of all legal rights, including that of owning property. The stipulations of the decree were difficult to enforce immediately, and the church remained a powerful social force for several years. The patriarch replied to the decree by excommunicating the "open or disguised enemies of Christ," without naming the government specifically. He also made pronouncements on political issues that he considered of moral importance: in March 1918 he condemned the peace of Brest-Litovsk that brought an unsatisfactory armistice between Russia and the Central Powers, and in October he addressed an "admonition" to Lenin, calling on him to proclaim an amnesty. Tikhon was careful, however, not to appear as a counterrevolutionary and in September 1919 called the faithful to refrain from supporting the Whites (anti-Communists) and to obey those decrees of the Soviet government that were not contrary to their Christian conscience.

The independence of the church suffered greatly after 1922. In February of that year, the government decreed the confiscation of all valuable objects preserved in the churches. The patriarch would have agreed to that measure if he had had the means to check on the government contention that all confiscated church property would be used to help the starving population on the Volga. The government refused all guarantees but supported a group of clergy who were ready to cooperate with it and to overthrow the patriarch. While Tikhon was under house arrest, this group took over his office and soon claimed the allegiance of a sizable proportion of bishops and clergy. This became known as the schism of the "Renovated" or "Living" Church, and it broke the internal unity and resistance of the church. Numerous bishops and clergy faithful to the patriarch were tried and executed, including the young and progressive metropolitan Benjamin of Petrograd. The "Renovated" Church soon broke the universal discipline of Orthodoxy by admitting married priests to the episcopate and by permitting widowed priests to remarry.

Upon his release, Tikhon condemned the schismatics, and many clergy returned to his obedience. But he also published a declaration affirming that he "was not the enemy of the Soviet government" and dropped any opposition to the authorities. Tikhon's attitude of conformism did not bring immediate results. His designated successors (after he died in 1925) were all arrested. In 1927 the "substitute *locum tenens*" (holder of the position) of the patriarchate, Metropolitan Sergius, pledged loyalty to the Soviet government. Nevertheless, under the rule of Joseph Stalin in the late 1920s and '30s, the church suffered a bloody persecution that claimed thousands of victims. By 1939 only three or four Orthodox bishops and 100 churches could officially function: the church was practically suppressed.

A spectacular reversal of Stalin's policies occurred, however, during World War II. Sergius was elected patriarch in 1943 and the "Renovated" schism was ended. Under Sergius' successor, Patriarch Alexis (1945–70), the church was able to open 25,000 churches and the number of priests reached 33,000. But a new antireligious move was initiated by Prime Minister Nikita Khrushchev in 1959–64, reducing the number of open churches to less than 10,000. Patriarch Pimen was elected in 1971 following Alexis' death, and, although the church still commanded the loyalty of millions, its future remained uncertain.

Post-World War II developments in the Soviet Union

After 70 years of repression and antireligious propaganda, however, the church experienced greater religious freedom in the late 1980s, culminating with the dissolution of the Soviet Union in 1991.

The Balkans and eastern Europe. In bringing about the fall of the Turkish, Austrian, and Russian empires, World War I provoked significant changes in the structures of the Orthodox Church. On the western borders of what was then the Soviet Union, in the newly born republics of Finland, Estonia, Latvia, and Lithuania, the Orthodox minorities established themselves as autonomous churches. The first three joined the jurisdiction of Constantinople, and the Lithuanian diocese remained nominally under Moscow. In Poland, which then included several million Belorussians and Ukrainians, the ecumenical patriarch established an autocephalous church (1924) over the protests of Patriarch Tikhon. After World War II the Estonian, Latvian, and Lithuanian autonomies were again suppressed, and in Poland the Orthodox Church was first reintegrated to the jurisdiction of Moscow and later was declared autocephalous again (1948).

In the Balkans, changes were even more significant. The five groups of Serbian dioceses (Montenegro, patriarchate of Karlovci, Dalmatia, Bosnia-Herzegovina, Old Serbia) were united (1920–22) under one Serbian patriarch, residing in Belgrade, the capital of the new Yugoslavia. Similarly, the Romanian dioceses of Moldavia-Walachia, Transylvania, Bukovina, and Bessarabia formed the new patriarchate of Romania (1925), the largest autocephalous church in the Balkans. Finally, in 1937, after some tension and a temporary schism, the patriarchate of Constantinople recognized the autocephaly of the Church of Albania.

Relations between church and state in the Balkans

After World War II, Communist regimes were established in the Balkan states. There were no attempts, however, at liquidating the churches entirely, similar to the persecutions that took place in Russia in the 1920s and '30s. In both Yugoslavia and Bulgaria, church and state were legally separated. In Romania, paradoxically, the Orthodox Church remained legally linked to the Communist state. With its solid record of resistance to the Germans, the Serbian Church was able to preserve more independence from the government than its sister churches of Bulgaria and Romania. Generally speaking, however, all the Balkan churches adopted an attitude of loyalty to the new regime, according to the pattern given by the patriarchate of Moscow. At that price, they could keep some theological schools, some publications, and the possibility to worship. This is also the case of the Orthodox minority in Czechoslovakia, which was united and organized into an autocephalous church by the patriarchate of Moscow in 1951. Only in Albania did a Communist government announce the total liquidation of organized religion, following the Cultural Revolution of 1966–68.

Among the national Orthodox churches, the Church of Greece is the only one that preserved the legal status it acquired in the 19th century as the national state church. As such, it was supported by the successive political regimes of Greece. It could also develop an impressive internal mission. The Brotherhood Zoe ("Life"), organized according to the pattern of Western religious orders, was successful in creating a large system of church schools.

The Communist governments throughout eastern Europe collapsed during the late 1980s and early 1990s, effectively dissolving state control over churches and bringing new political and religious freedoms into the region.

The Orthodox Church in the Middle East. As a result of the Greco-Turkish War, the entire Greek population of Asia Minor was transferred to Greece (1922); the Orthodox

Conditions of the Eastern patriarchates

under the immediate jurisdiction of the ecumenical patriarchate of Constantinople were thus reduced to the Greek population of Istanbul and its vicinity. This population, rapidly shrinking in recent years, is now reduced to a few thousand. Still recognized as holding an honorary primacy among the Orthodox churches, the ecumenical patriarchate also exercises jurisdiction over several dioceses of the "diaspora" and, by consent of the Greek government, over the Greek islands. The impressive personality of Patriarch Athenagoras I (1948–72), who was succeeded by Dimitrios, contributed to its prestige on the pan-Orthodox and ecumenical levels. The patriarchate convened pan-Orthodox conferences in Rhodes, Belgrade, Geneva, and other cities and began preparations for a "Great Council" of the Orthodox Church.

Together with the ecumenical patriarchate, the ancient sees of Alexandria, Antioch, and Jerusalem are remnants of the Byzantine imperial past, but under the present conditions they still possess many opportunities of development: Alexandria, as the centre of emerging African communities (see below *The Orthodox diaspora and missions*); Antioch, as the largest Arab Christian group, with dioceses in Syria, Lebanon, and Iraq; and Jerusalem, as the main custodian of the Christian holy places in that city.

The two ancient churches of Cyprus and Georgia, with their quite peculiar history, continue to play important roles among the Orthodox sister churches. Autocephalous since 431, the Church of Cyprus survived the successive occupations, and often oppressions, by the Arabs, the Crusaders, the Venetians, the Turks, and the English. Following the pattern of all areas where Islām was predominant, the archbishop is traditionally seen as the ethnarch of the Greek Christian Cypriots. Archbishop Makarios also became the first president of the independent Republic of Cyprus in 1960. The Church of Georgia, isolated in the Caucasus in a country that became part of the Russian Empire in 1801, is the witness of one of the most ancient Christian traditions. It received autocephaly from its mother Church of Antioch as early as the 6th century and developed a literary and artistic civilization in its own language. Its head bears the traditional title of "Catholicos-Patriarch." When the Russians annexed the country in 1801, they suppressed Georgia's autocephaly and the church was governed by a Russian "exarch" until 1917 when the Georgians reestablished their ecclesiastical independence. Fiercely persecuted during the 1920s, the Georgian Church survives to the present day as an autocephalous patriarchate.

Orthodoxy in the United States. The first Orthodox communities in what is today the continental United States were established in Alaska and on the West Coast, as the extreme end of the Russian missionary expansion through Siberia (see above *The church in imperial Russia*). Russian monks settled on Kodiak Island in 1794. Among them was St. Herman (died 1837, canonized 1970), an ascetic and a defender of the natives' rights against their exploitation by ruthless Russian traders. After the sale of Alaska to the United States, a separate diocese "of the Aleutian Islands and Alaska" was created by the Holy Synod (1870). After the transfer of the diocesan centre to San Francisco and its renaming as the diocese "of the Aleutian Islands and North America" (1900), the original church establishment exercised its jurisdiction on the entire North American continent. In the 1880s, it accepted back into Orthodoxy hundreds of "Uniate" parishes of immigrants from Galicia and Carpatho-Russia, particularly numerous in the northern industrial states and in Canada. It also served the needs of immigrants from Serbia, Greece, Syria, Albania, and other countries. Some Greek and Romanian communities, however, invited priests directly from the mother country without official contact with the American bishop. In 1905 the American archbishop Tikhon (future patriarch of Moscow) presented to the Russian synod the project of an autonomous, or autocephalous, church of America, whose structure would reflect the ethnic pluralism of its membership. He also foresaw the inevitable Americanization of his flock and encouraged the translation of the liturgy into English.

Organization and canonical status of American Orthodox churches

These projects, however, were hampered by the tragedies that befell the Russian Church following the Russian Revolution. The administrative system of the Russian Church collapsed. The non-Russian groups of immigrants sought and obtained their affiliation with mother churches abroad. In 1921 a "Greek Archdiocese of North and South America" was established by the ecumenical patriarch Meletios IV Metaxakis. Further divisions within each national group occurred repeatedly, and several independent jurisdictions added to the confusion.

A reaction against this chaotic pluralism manifested itself in the 1950s. More cooperation between the jurisdictions and a more systematic theological education contributed to an increased desire for unity. A Standing Conference of Canonical Orthodox Bishops in the Americas was established in 1960. In 1970 the patriarch of Moscow, reviving Tikhon's project of 1905, formally proclaimed its diocese in America (which had been in conflict with Moscow since 1931 on the issue of "loyalty" to the Soviet Union) as the autocephalous Orthodox Church in America, totally independent from administrative connections abroad. The ecumenical patriarchate of Constantinople, however, protested this move, turned down a request for autonomy presented by the Greek archdiocese (the largest single Orthodox body in the United States), and reiterated its opposition to the use of English in the liturgy (1970). This latest crisis of American Orthodoxy involves the very understanding of the Orthodox presence in the Western world, centring on the question of the utility of preserving the ethnic ties of the past.

The Orthodox diaspora and missions. Since World War I, millions of east Europeans were dispersed in various areas where Orthodox communities had never existed before. The Russian Revolution provoked a massive political emigration, predominantly to western Europe and particularly France. It included eminent churchmen, theologians, and Christian intellectuals, such as Bulgakov, Berdyayev, and V.V. Zenkovsky, who were able not only to establish in Paris a theological school of great repute but also to contribute significantly to the ecumenical movement. In 1922 Patriarch Tikhon appointed Metropolitan Evlogy to head the émigré churches, with residence in Paris. The authority of the metropolitan was challenged, however, by a group of bishops who had left their sees in Russia, retreating with the White armies, and who had found refuge in Sremski-Karlovci as guests of the Serbian Church. Despite several attempts at reconciliation, the "Synod" of Karlovci, proclaiming its firm attachment to the principle of tsarist monarchy, refused to recognize any measure taken by the reestablished patriarchate of Moscow. This group transferred its headquarters to New York and is also known as the "Russian Orthodox Church outside of Russia." It has no canonical relation with the official Orthodox patriarchates and churches. A "Ukrainian Orthodox Church in exile" finds itself in a similarly irregular canonical situation. Other émigré groups found refuge under the canonical auspices of the ecumenical patriarchate.

Theological and missionary activities after World War I

After World War II, a very numerous Greek emigration took place to western Europe, Australia, New Zealand, and Africa. In East Africa, without much initial effort on their part, these Greek-speaking emigrants have attracted a sizable number of black Christians, who have discovered in the Orthodox liturgy and sacramental worship a form of Christianity more acceptable to them than the more dogmatic institutions of Western Christianity. Also, in their eyes, Orthodoxy has the advantage of having no connection with the colonial regimes of the past. Orthodox communities, with an ever increasing number of native clergy, are spreading in Uganda, Kenya, and Tanzania. Less professionally planned than the former Russian missions in Alaska and Japan, these young churches constitute an interesting development in African Christianity.

Ecumenical involvement. Between the two world wars, many Orthodox churchmen of the ecumenical patriarchate of Constantinople, of Greece, of the Balkan churches, and of the Russian emigration took part in the ecumenical movement. After World War II, however, the churches of the Communist-dominated countries failed to join the newly created World Council of Churches (1948): only Constantinople and Greece did so. The situation changed

drastically in 1961, when the patriarchate of Moscow applied for membership and was soon followed by other autocephalous churches. Before and after 1961, the Orthodox consistently declared that their membership did not imply any relativistic understanding of the Christian truth, but that they were ready to discuss with all Christians the best way of restoring the lost unity of Christendom, as well as problems of common Christian action and witness in the modern world.

During the reign of Pope John XXIII, when Roman Catholicism became actively involved in ecumenism, the Orthodox—after some hesitation—contributed to the new atmosphere. The spectacular meetings in the 1960s between Patriarch Athenagoras and the Pope in Jerusalem, Istanbul, and Rome, the symbolic lifting of ancient anathemas, and other gestures were signs of rapprochement, although they are sometimes mistakenly interpreted as if they were ending the Schism itself. In the Orthodox view, full unity can be restored only in the fullness of truth witnessed by the entire church and sanctioned in sacramental communion.

Doctrine

COUNCILS AND CONFESSIONS

All Orthodox credal formulas, liturgical texts, and doctrinal statements affirm the claim that the Orthodox Church has preserved the original apostolic faith, which was also expressed in the common Christian tradition of the first centuries. The Orthodox Church recognizes as ecumenical the seven councils of Nicaea I (325), Constantinople I (381), Ephesus (431), Chalcedon (451), Constantinople II (553), Constantinople III (681), and Nicaea II (787) but considers that the decrees of several other later councils also reflect the same original faith (*e.g.*, the councils of Constantinople that endorsed the theology of St. Gregory Palamas in the 14th century). Finally, it recognizes itself as the bearer of an uninterrupted living tradition of true Christianity that is expressed in its worship, in the lives of the saints, and in the faith of the whole people of God.

The first seven ecumenical councils

In the 17th century, as a counterpart to the various "confessions" of the Reformation, there appeared several "Orthodox confessions," endorsed by local councils but, in fact, associated with individual authors (*e.g.*, Metrophanes Critopoulos, 1625; Peter Mogila, 1638; Dosítheos of Jerusalem, 1672). None of these confessions would be recognized today as having anything but historical importance. When expressing the beliefs of his church, the Orthodox theologian, rather than seeking literal conformity with any of these particular confessions, will rather look for consistency with Scripture and tradition, as it has been expressed in the ancient councils, the early Fathers, and the uninterrupted life of the liturgy. He will not shy away from new formulations if consistency and continuity of tradition are preserved.

What is particularly characteristic of this attitude toward the faith is the absence of any great concern for establishing external *criteria* of truth—a concern that has dominated Western Christian thought since the Middle Ages. Truth appears as a living experience accessible in the communion of the church and of which the Scriptures, the councils, and theology are the normal expressions. Even ecumenical councils, in the Orthodox perspective, need subsequent "reception" by the body of the church in order to be recognized as truly ecumenical. Ultimately, therefore, truth is viewed as its own criterion: there are signs that point to it, but none of these signs is a substitute for a free and personal experience of truth, which is made accessible in the sacramental fellowship of the church.

The criterion of truth

Because of this view of truth, the Orthodox have traditionally been reluctant to involve church authority in defining matters of faith with too much precision and detail. This reluctance is not due to relativism or indifference but rather to the belief that truth needs no definition to be the object of experience and that legitimate definition, when it occurs, should aim mainly at excluding error and not at pretending to reveal the truth itself that is believed to be ever present in the church.

GOD AND MAN

The development of the doctrines concerning the Trinity and the incarnation, as it took place during the first eight centuries of Christian history, was related to the concept of man's *participation* in divine life.

The Greek Fathers of the church always implied that the phrase found in the biblical story of the creation of man (Gen. 1:26), according to "the image and likeness of God," meant that man is not an autonomous being and that his ultimate nature is defined by his relation to God, his "prototype." In paradise Adam and Eve were called to participate in God's life and to find in him the natural growth of their humanity "from glory to glory." To be "in God" is, therefore, the *natural* state of man. This doctrine is particularly important in connection with the Fathers' view of human freedom. For theologians such as Gregory of Nyssa (4th century) and Maximus the Confessor (7th century) man is truly free only when he is in communion with God; otherwise he is only a slave to his body or to "the world," over which, originally and by God's command, he was destined to rule.

Human freedom and sin

Thus, the concept of *sin* implies separation from God and the reduction of man to a separate and autonomous existence, in which he is deprived of both his natural glory and his freedom. He becomes an element subject to cosmic determinism, and the image of God is thus blurred within him.

Freedom in God, as enjoyed by Adam, implied the possibility of falling away from God. This is the unfortunate choice made by man, which led Adam to a subhuman and unnatural existence. The most unnatural aspect of his new state was death. In this perspective, "original sin" is understood not so much as a state of guilt inherited from Adam but as an unnatural condition of human life that ends in death. Mortality is what each man now inherits at his birth and this is what leads him to struggle for existence, to self-affirmation at the expense of others, and ultimately to subjection to the laws of animal life. The "prince of this world" (*i.e.*, Satan), who is also the "murderer from the beginning," has dominion over man. From this vicious circle of death and sin, man is understood to be liberated by the death and Resurrection of Christ, which is actualized in Baptism and the sacramental life in the church.

The general framework of this understanding of the God–man relationship is clearly different from the view that became dominant in the Christian West—*i.e.*, the view that conceived of "nature" as distinct from "grace" and that understood original sin as an inherited guilt rather than as a deprivation of freedom. In the East, man is regarded as fully man when he participates in God; in the West, man's nature is believed to be autonomous, sin is viewed as a punishable crime, and grace is understood to grant forgiveness. Hence, in the West, the aim of the Christian is justification, but in the East, it is rather communion with God and deification. In the West, the church is viewed in terms of mediation (for the bestowing of grace) and authority (for guaranteeing security in doctrine); in the East, the church is regarded as a communion in which God and man meet once again and a personal experience of divine life becomes possible.

Deification

CHRIST

The Orthodox Church is formally committed to the Christology (doctrine of Christ) that was defined by the councils of the first eight centuries. Together with the Latin Church of the West, it has rejected Arianism (a belief in the subordination of the Son to the Father) at Nicaea (325), Nestorianism (a belief that stresses the independence of the divine and human natures of Christ) at Ephesus (431), and Monophysitism (a belief that Christ had only one divine nature) at Chalcedon (451). The Eastern and Western churches still formally share the tradition of subsequent Christological developments, even though the famous formula of Chalcedon, "one person in two natures," is given different emphases in the East and West. The stress on Christ's identity with the preexistent Son of God, the Logos (Word) of the Gospel According to John, characterizes Orthodox Christology. On Byzantine icons, around the

Logos as the Christ

face of Jesus, the Greek letters ὁ ὢν—the equivalent of the Jewish Tetragrammaton YHWH, the name of God in the Old Testament—are often depicted. Jesus is thus always seen in his divine identity. Similarly, the liturgy consistently addresses the Virgin Mary as Theotokos (the "one who gave birth to God"), and this term, formally admitted as a criterion of orthodoxy at Ephesus, is actually the only "Mariological" (doctrine of Mary) dogma accepted in the Orthodox Church. It reflects the doctrine of Christ's unique divine Person, and Mary is thus venerated only because she is his mother "according to the flesh."

This emphasis on the personal divine identity of Christ, based on the doctrine of St. Cyril of Alexandria (5th century), does not imply the denial of his humanity. The anthropology (doctrine of man) of the Eastern Fathers does not view man as an autonomous being but rather implies that communion with God makes man fully human. Thus the human nature of Jesus Christ, fully assumed by the divine Word, is indeed the "new Adam" in whom the whole of humanity receives again its original glory. Christ's humanity is fully "ours"; it possessed all the characteristics of the human being—"each nature (of Christ) acts according to its properties," Chalcedon proclaimed, following Pope Leo—without separating itself from the divine Word. Thus, in death itself—for Jesus' death was indeed a fully human death—the Son of God was the "subject" of the Passion. The theopaschite formula ("God suffered in the flesh") became, together with the Theotokos formula, a standard of orthodoxy in the Eastern Church, especially after the second Council of Constantinople (553). It implied that Christ's humanity was indeed real not only in itself but also for God, since it brought him to death on the cross, and that the salvation and redemption of humanity can be accomplished by God alone—hence the necessity for him to condescend to death, which held humanity captive.

Theology of salvation and redemption

This theology of redemption and salvation is best expressed in the Byzantine liturgical hymns of Holy Week and Easter: Christ is the one who "tramples down death by death," and, on the evening of Good Friday, the hymns already exalt his victory. Salvation is conceived not in terms of satisfaction of divine justice, through paying the debt for the sin of Adam—as the medieval West understood it—but in terms of uniting the human and the divine with the divine overcoming human mortality and weakness and, finally, exalting man to divine life.

What Christ accomplished once and for all must be appropriated freely by those who are "in Christ"; their goal is "deification," which does not mean dehumanization but the exaltation of man to the dignity prepared for him at creation. Such feasts as the Transfiguration or the Ascension are extremely popular in the East precisely because they celebrate humanity glorified in Christ—a glorification that anticipates the coming of the Kingdom of God, when God will be "all in all."

Participation in the already deified humanity of Christ is the true goal of Christian life, and it is accomplished through the Holy Spirit.

THE HOLY SPIRIT

The gift of the Holy Spirit at Pentecost "called all men into unity," according to the Byzantine liturgical hymn of the day; into this new unity, which St. Paul called the "body of Christ," each individual Christian enters through Baptism and "chrismation" (the Eastern form of the Western "confirmation") when the priest anoints him saying "the seal of the gift of the Holy Spirit."

This gift, however, requires man's free response. Orthodox saints such as Seraphim of Sarov (died 1833) described the entire content of Christian life as a "collection of the Holy Spirit." The Holy Spirit is thus conceived as the main agent of man's restoration to his original natural state through Communion in Christ's body. This role of the Spirit is reflected, very richly, in a variety of liturgical and sacramental acts. Every act of worship usually starts with a prayer addressed to the Spirit, and all major sacraments begin with an invocation to the Spirit. The eucharistic liturgies of the East attribute the ultimate mystery of Christ's Presence to a descent of the Spirit upon the worshipping congregation and upon the eucharistic bread and wine. The significance of this invocation (in Greek *epiklēsis*) was violently debated between Greek and Latin Christians in the Middle Ages because the Roman canon of the mass lacked any reference to the Spirit and was thus considered as deficient by the Orthodox Greeks.

The Holy Spirit as the agent of restoration

Since the Council of Constantinople (381), which condemned the Pneumatomachians ("fighters against the Spirit"), no one in the Orthodox East has ever denied that the Spirit is not only a "gift" but also the giver—*i.e.*, that he is the third Person of the holy Trinity. The Greek Fathers saw in Gen. 1:2 a reference to the Spirit's cooperation in the divine act of creation; the Spirit was also viewed as active in the "new creation" that occurred in the womb of the Virgin Mary when she became the mother of Christ (Luke 1:35); and finally, Pentecost was understood to be an anticipation of the "last days" (Acts 2:17) when, at the end of history, a universal communion with God will be achieved. Thus, all the decisive acts of God are accomplished "by the Father in the Son, through the Holy Spirit."

THE HOLY TRINITY

By the 4th century a polarity developed between the Eastern and Western Christians in their respective understandings of the Trinity. In the West God was understood primarily in terms of one essence (the Trinity of Persons being conceived as an irrational truth found in revelation); in the East the tri-personality of God was understood as the *primary* fact of Christian experience. For most of the Greek Fathers, it was not the Trinity that needed theological proof but rather God's essential unity. The Cappadocian Fathers (Gregory of Nyssa, Gregory of Nazianzus, and Basil of Caesarea) were even accused of being tri-theists because of the personalistic emphasis of their conception of God as one essence in three hypostases (the Greek term *hypostasis* was the equivalent of the Latin *substantia* and designated a concrete reality). For Greek theologians, this terminology was intended to designate the concrete New Testamental revelation of the Son and the Spirit, as distinct from the Father.

Modern Orthodox theologians tend to emphasize this personalistic approach to God; they claim that they discover in it the original biblical personalism, unadulterated in its content by later philosophical speculation.

The *Filioque* controversy

Polarization of the Eastern and the Western concepts of the Trinity is at the root of the *Filioque* dispute. The Latin word *Filioque* ("and from the Son") was added to the Nicene Creed in Spain in the 6th century. By affirming that the Holy Spirit proceeds not only "from the Father" (as the original creed proclaimed) but also "from the Son," the Spanish councils intended to condemn Arianism by reaffirming the Son's divinity. Later, however, the addition became an anti-Greek battle cry, especially after Charlemagne (9th century) made his claim to rule the revived Roman Empire. The addition was finally accepted in Rome under German pressure. It found justification in the framework of Western conceptions of the Trinity; the Father and the Son were viewed as one God in the act of "spiration" of the Spirit.

The Byzantine theologians opposed the addition, first on the ground that the Western Church had no right to change the text of an ecumenical creed unilaterally and, second, because the *Filioque* clause implied the reduction of the divine persons to mere relations ("the Father and the Son are two in relation to each other, but one in relation to the Spirit"). For the Greeks the Father alone is the origin of both the Son and the Spirit. Patriarch Photius (9th century) was the first Orthodox theologian to explicitly spell out the Greek opposition to the *Filioque* concept, but the debate continued throughout the Middle Ages.

THE TRANSCENDENCE OF GOD

An important element in the Eastern Christian understanding of God is the notion that God, in his essence, is totally transcendent and unknowable and that, strictly speaking, God can only be designated by negative attributes: it is possible to say what God is not, but it is impossible to say what he is.

Apophatic theology

A purely negative, or "apophatic" theology—the only one applicable to the *essence* of God in the Orthodox view—does not lead to agnosticism, however, because God reveals himself personally—as Father, Son, and Holy Spirit—and also in his *acts*, or "energies." Thus, true knowledge of God always includes three elements: religious awe; personal encounter; and participation in the acts, or energies, which God freely bestows on creation.

This conception of God is connected with the personalistic understanding of the Trinity. It also led to the official confirmation by the Orthodox Church of the theology of St. Gregory Palamas, the leader of Byzantine hesychasts (monks devoted to divine quietness through prayer), at the councils of 1341 and 1351 in Constantinople. The councils confirmed a real distinction in God, between the unknowable essence and the acts, or "energies," which make possible a real communion with God. The deification of man, realized in Christ once and for all, is thus accomplished by a communion of divine energy with humanity in Christ's glorified manhood.

MODERN THEOLOGICAL DEVELOPMENTS

Until the conquest of Constantinople by the Turks (1453), Byzantium was the unquestioned intellectual centre of the Orthodox Church. Far from being monolithic, Byzantine theological thought was often polarized by a Humanistic trend, favouring the use of Greek philosophy in theological thinking, and the more austere and mystical theology of the monastic circles. The concern for preservation of Greek culture and for the the political salvation of the empire led several prominent Humanists to adopt a position favourable to union with the West. The most creative theologians (*e.g.*, Symeon the New Theologian, died 1033; Gregory Palamas, died 1359; Nicholas Cabasilas, died *c.* 1390), however, were found rather in the monastic party that continued the tradition of patristic spirituality based upon the theology of deification.

The dark age of Orthodox theology

The 16th, 17th, and 18th centuries were the dark age of Orthodox theology. Neither in the Middle East nor in the Balkans nor in Russia was there any opportunity for independent theological creativity. Since no formal theological education was accessible, except in Western Roman Catholic or Protestant schools, the Orthodox tradition was preserved primarily through the liturgy, which retained all its richness and often served as a valid substitute for formal schooling. Most doctrinal statements of this period, issued by councils or by individual theologians, were polemical documents directed against Western missionaries.

After the reforms of Peter the Great (died 1725), a theological school system was organized in Russia. Shaped originally in accordance with Western Latin models and staffed with Jesuit-trained Ukrainian personnel, this system developed, in the 19th century, into a fully independent and powerful tool of theological education. The Russian theological efflorescence of the 19th and 20th centuries produced many scholars, especially in the historical field (*e.g.*, Philaret Drozdov, died 1867; V.O. Klyuchevsky, died 1913; V.V. Bolotov, died 1900; E.E. Golubinsky, died 1912; N.N. Glubokovsky, died 1937). Independently of the official theological schools, a number of laymen with secular training developed theological and philosophical traditions of their own and exercised a great influence on modern Orthodox theology (*e.g.*, A.S. Khomyakov, died 1860; V.S. Solovyev, died 1900; N. Berdyayev, died 1948), and some became priests (P. Florensky, died 1943; S. Bulgakov, died 1944). A large number of the Russian theological intelligentsia (*e.g.*, S. Bulgakov, G. Florovsky) emigrated to western Europe after the Russian Revolution (1917) and played a leading role in the ecumenical movement.

With the independence of the Balkans, theological schools were also created in Greece, Serbia, Bulgaria, and Romania. Modern Greek scholars contributed to the publication of important Byzantine ecclesiastical texts and produced standard theological textbooks.

The Orthodox diaspora

The Orthodox diaspora—the emigration from eastern Europe and the Middle East—in the 20th century has contributed to modern theological development through their establishment of theological centres in western Europe and America.

Orthodox theologians reacted negatively to the new dogmas proclaimed by Pope Pius IX: the Immaculate Conception of Mary (1854) and papal infallibility (1870). In connection with the dogma of the Assumption of Mary, proclaimed by Pope Pius XII (1950), the objections mainly concerned the presentation of such a tradition in the form of a dogma.

In contrast to the recent general trend of Western Christian thought toward social concerns, Orthodox theologians generally emphasize that the Christian faith is primarily a direct experience of the Kingdom of God, sacramentally present in the church. Without denying that Christians have a social responsibility to the world, they consider this responsibility as an outcome of the life in Christ. This traditional position accounts for the remarkable survival of the Orthodox Churches under the most contradictory and unfavourable of social conditions, but, to Western eyes, it often appears as a form of passive fatalism.

The structure of the church

THE CANONS

The permanent criteria of church structure for the Orthodox Church today, outside of the New Testament writings, are found in the canons (regulations and decrees) of the first seven ecumenical councils; the canons of several local or provincial councils, whose authority was recognized by the whole church; the so-called *Apostolic Canons* (actually some regulations of the church in Syria, dating from the 4th century); and the "canons of the Fathers," or selected extracts from prominent church leaders having canonical importance.

The nomocanon

A collection of these texts was made in the Byzantine nomocanon, attributed, in its final form, to the patriarch Photius (9th century). The Byzantine Church, as well as the modern Orthodox Churches, has adapted the general principles of this collection to its particular situation, and the local autocephalous churches govern themselves according to their own particular statutes, although all accept the ancient canons as their common canonical reference.

The canons themselves do not represent a system or a code. They do, however, reflect a consistent view of the church, of its mission, and of its various ministries; they also reflect an evolution of ecclesiastical structure—*i.e.*, the growth of centralization in the framework of the Christian Roman Empire. For the Orthodox Church today, only the original self-understanding of the church has a theologically normative value. Thus, those canons that reflect the nature of the church as the body of Christ have an unchanging validity today; other canons, if they can be recognized as conditioned by the historical situation in which they were issued, are subject to change by conciliar authority; others have simply fallen out of practice. The use and interpretation of the canons is therefore possible only in the light of some understanding of the church's nature. This theological dimension is the ultimate criterion through which it is possible to distinguish what is permanent in the canons from that which represents no more than a historical value.

THE EPISCOPATE

The Orthodox understanding of the church is based on the principle, attested to in the canons and in early Christian tradition, that each local community of Christians, gathered around its bishop and celebrating the Eucharist, is the local realization of the *whole* body of Christ. "Where Christ is, there is the Catholic church," wrote Ignatius of Antioch (*c.* AD 100). Modern Orthodox theology also emphasizes that the office of the bishop is the highest among the sacramental ministries and that there is therefore no divinely established authority *over* that of the bishop in his own community, or diocese. Neither the local churches nor the bishops, however, can or should live in isolation. The wholeness of church life, realized in each local community, is regarded as identical with that of the other local churches in the present and in the past. This identity and continuity is manifested in the act of the ordination of bishops, an act that requires the presence of several other

bishops in order to constitute a conciliar act and to witness to the continuity of apostolic succession and tradition.

The bishop is primarily the guardian of the faith and, as such, the centre of the sacramental life of the community. The Orthodox Church maintains the doctrine of apostolic succession—*i.e.*, the idea that the ministry of the bishop must be in direct continuity with that of the Apostles of Jesus. Orthodox tradition—as expressed especially in its medieval opposition to the Roman papacy—distinguishes the office of the "Apostle" from that of the bishop, however, in that the first is viewed as a universal witness to the historic Jesus and his Resurrection, while the latter is understood in terms of the pastoral and sacramental responsibility for a local community, or church. The continuity between the two is, therefore, a continuity in faith rather than in function. This Orthodox concept of the doctrine of apostolic succession has received wider exposure in Western churches recently because of increased encounters and consultations between Orthodox and Anglican churchmen, the Orthodox always emphasizing unity of faith as a prerequisite for recognition, on their part, of the "validity" of Anglican orders.

Apostolic succession

No bishop can be consecrated or exercise his ministry without being in unity with his colleagues—*i.e.*, be a member of an episcopal council, or "synod." After the Council of Nicaea (325), whose canons are still effective in the Orthodox Church, each province of the Roman Empire had its own synod of bishops that acted as a fully independent unit for the consecration of new bishops and also as a high ecclesiastical tribunal. In the contemporary Orthodox Church these functions are fulfilled by the synod of each autocephalous church. In the early church the bishop of the provincial capital acted as chairman of the synod and was generally called "metropolitan." Today this function is fulfilled by the local primate who is sometimes called "patriarch" (in the autocephalous churches of Constantinople, Alexandria, Antioch, Jerusalem, Russia, Georgia, Serbia, Romania, and Bulgaria), but he may also carry the title of archbishop (Cyprus, Greece) or metropolitan (Poland, the Czech and Slovak republics, America). The titles of archbishop and metropolitan are also widely used as honorific distinctions.

Generally, but not always, the jurisdiction of each autocephalous synod coincides with national borders—the exceptions are numerous in the Middle East (*e.g.*, jurisdiction of Constantinople over the Greek islands, jurisdiction of Antioch over several Arab states, etc.)—and concerns also the national dioceses of the Orthodox diaspora (*e.g.*, western Europe, Australia, America), which frequently remain under the authority of their mother churches. The latter situation led to an uncanonical overlapping of Orthodox jurisdictions, all based on ethnic origins. Several factors, going back to the Middle Ages, have contributed to modern ecclesiastical nationalism in the Orthodox Church. These factors include the use of the vernacular in the liturgy and the subsequent identification of religion with national culture; this identification sometimes helps the survival of the church under adverse political conditions, but it also hampers missionary expansion and the sense of a specifically Christian identity of the faithful.

CLERGY AND LAITY

The emphasis on communion and fellowship, as the basic principle of church life, inhibited the development of clericalism. The early Christian practice of having the laity participate in episcopal elections never disappeared completely in the East. In modern times, it has been restored in several churches. The Moscow Council of 1917–1918 introduced it in Russia, even if the events of the Revolution prevented its full implementation. Bishops are also elected by clergy-laity conventions in America and in other areas of the Orthodox world.

Clerical marriage

The lower orders of the clergy—*i.e.*, priests and deacons—are generally married men. The present canonical legislation allows the ordination of married men to the diaconate and the priesthood, provided that they were married only once and that their wives are neither widows nor divorcees. These stipulations reflect the general principle of absolute monogamy, which the Eastern Church considered as a Christian norm to which candidates for the priesthood are to comply strictly. Deacons and priests cannot marry after their ordination.

Bishops, however, are selected from among the unmarried clergy or widowed priests. The rule defining the requirement for an unmarried episcopate was issued at a time (6th century) when monks represented the elite of the clergy. The contemporary decrease in the number of monks in the Orthodox Church has created a serious problem in some territorial churches, in that new candidates for the episcopacy are difficult to find.

Besides being admitted, at least in some areas, to participation in episcopal elections, Orthodox laymen often occupy positions in church administration and in theological education. In Greece almost all professional theologians are laymen. Laymen also frequently serve as preachers.

MONASTICISM

The tradition of Eastern Christian monasticism goes back to the 3rd and 4th centuries of the Christian Era. From its beginning it was essentially a contemplative movement seeking the experience of God in a life of permanent prayer. This contemplative character has remained its essential feature throughout the centuries. Eastern Christianity never experienced the development of religious orders, pursuing particular missionary or educational goals and organized on a universal scale, as did Western Christianity.

Concern for prayer, as the central and principal function of monasticism, does not mean that the Eastern Christian monastic movement was of a single uniform character. Eremitic (solitary) monasticism, favouring the personal and individual practice of prayer and asceticism, often competed with "cenobitic" (communal) monastic life, in which prayer was mainly liturgical and corporate. The two forms of monasticism originated in Egypt and coexisted in Byzantium, as well as throughout eastern Europe.

Eremitic and cenobitic monasticism

In Byzantium the great monastery of Studion became the model of numerous cenobitic communities (see above under *History: The church of imperial Byzantium*). It is in the framework of the eremitic, or Hesychast, tradition, however, that the most noted Byzantine mystical theologians (*e.g.*, Symeon the New Theologian, Gregory Palamas, etc.) received their training. One of the major characteristics of the Hesychast tradition is the practice of the "Jesus prayer," or constant invocation of the name of Jesus, sometimes in connection with breathing. This practice won wide acceptance in medieval and modern Russia.

Cenobitic traditions of Byzantium also were important in Slavic lands. The colonization of the Russian north was largely accomplished by monks who acted as pioneers of civilization and as missionaries.

In Byzantium, as well as in other areas of the Orthodox world, the monks were often the only upholders of the moral and spiritual integrity of Christianity, and thus they gained the respect of the masses, as well as that of the intellectuals. The famous Russian *startsy* ("elders") of the 19th century became the spiritual leaders of Dostoyevsky, Gogol, and Tolstoy and inspired many religious philosophers in their quest for religious experience.

Today the most famous, though declining, centre of Orthodox monasticism is Mt. Athos (Greece), where over a thousand monks of different national backgrounds form a variety of communities, grouped into a monastic republic.

Worship and sacraments

THE ROLE OF THE LITURGY

By its theological richness, spiritual significance, and variety, the worship of the Orthodox Church represents one of the most significant factors in this church's continuity and identity. It helps to account for the survival of Christianity during the many centuries of Muslim rule in the Middle East and the Balkans when the liturgy was the only source of religious knowledge or experience. Since liturgical practice was practically the only religious expression legally authorized in the former Soviet Union, the continuous existence of Orthodox communities in the region was also centred almost exclusively around the liturgy.

The concept that the church is most authentically itself

Worship as the primary experience of Eastern Christianity

when the congregation of the faithful is gathered together in worship is a basic expression of Eastern Christian experience. Without that concept it is impossible to understand the fundamentals of church structure in Orthodoxy, with the bishop functioning in his essential roles of teacher and high priest in the liturgy. Similarly, the personal experience of man's participation in divine life is understood in the framework of the continuous liturgical action of the community.

According to many authorities, one of the reasons that helps to explain why the Eastern liturgy has made a stronger impact on the Christian Church than has its Western counterpart is that it has always been viewed as a total experience, appealing simultaneously to the emotional, intellectual, and aesthetic faculties of man. The liturgy includes a variety of models, or symbols, using formal theological statements as well as bodily perceptions and gestures (*e.g.,* music, incense, prostrations) or the visual arts. All are meant to convey the content of the Christian faith to the educated and the noneducated alike. Participation in the liturgy implies familiarity with its models, and many of them are conditioned by the historical and cultural past of the church. Thus, the use of such an elaborate and ancient liturgy presupposes catechetical preparation. It may require an updating of the liturgical forms themselves. The Orthodox Church recognizes that liturgical forms are changeable and that, since the early church admitted a variety of liturgical traditions, such a variety is also possible today. Thus, Orthodox communities with Western rites now exist in western Europe and in the Americas.

The Orthodox Church, however, has always been conservative in liturgical matters. This conservatism is due, in particular, to the absence of a central ecclesiastical authority that could enforce reforms and to the firm conviction of the church membership as a whole that the liturgy is the main vehicle and experience of true Christian beliefs. Consequently, reform of the liturgy is often considered as equivalent to a reform of the faith itself. However inconvenient this conservatism may be, the Orthodox liturgy has preserved many essential Christian values transmitted directly from the experience of the early church.

Throughout the centuries, the Orthodox liturgy has been richly embellished with cycles of hymns from a wide variety of sources. Byzantium (where the present Orthodox liturgical rite took shape), while keeping many biblical and early Christian elements, used the lavish resources of patristic theology and Greek poetry, as well as some gestures of imperial court ceremonial, in order to convey the realities of God's kingdom.

Normally, the content of the liturgy is directly accessible to the faithful, because the Byzantine tradition is committed to the use of any vernacular language in the liturgy. Translation of both Scriptures and liturgy into various languages was undertaken by the medieval Byzantines, as well as by modern Russian missionaries. Liturgical conservatism, however, leads de facto to the preservation of antiquated languages. The Byzantine Greek used in church services by the modern Greeks and the Old Slavonic still preserved by all the Slavs are at least as distant from the spoken languages as is the language of the King James Version—used in many Protestant Churches—from modern English.

THE EUCHARISTIC LITURGIES

Two eucharistic liturgies are most generally used in Orthodox worship—*i.e.,* the so-called liturgies of St. John Chrysostom and of St. Basil the Great. Both acquired their present shape by the 9th century, but it is generally recognized that the wording of the eucharistic "canon" of the liturgy of St. Basil goes back to the 4th century—*i.e.,* to St. Basil himself. The so-called Liturgy of St. James is used occasionally, especially in Jerusalem. During the period of Lent, a service of Communion, with elements (bread and wine) reserved from those consecrated on the previous Sunday, is celebrated in connection with the evening service of Vespers; it is called the "Liturgy of the Presanctified" and is attributed to St. Gregory the Great.

The liturgies of St. John Chrysostom and of St. Basil differ only in the text of the eucharistic canon: their overall structures, established in the high Middle Ages, are identical.

These eucharistic liturgies begin with an elaborate rite of preparation (*proskomidē*). A priest on a separate "table of oblation" disposes on a paten (plate) the particles of bread that will symbolize the assembly of the saints, both living and dead, around Christ, the "Lamb of God." Then follows the "Liturgy of the Catechumens," which begins with a processional entrance of the priest into the sanctuary with the Gospel (Little Entrance) and which includes the traditional Christian "liturgy of the word"—*i.e.,* the reading from the New Testament letters and the Gospels as well as a sermon. This part of the liturgy ends with the expulsion of the "catechumens," who, until they were baptized, were not admitted to the sacramental part of the service. The "Liturgy of the Faithful" includes another ceremonial procession of the priest into the sanctuary. He carries the bread and wine from the table of oblations to the altar (Great Entrance); the following recitation of the Nicene Creed, the eucharistic canon, the Lord's Prayer, and Communion are—as in the West—the characteristic parts of the Byzantine "Liturgy of the Faithful." The bread used for the Eucharist is ordinary leavened bread; both elements (bread and wine) are distributed with a special spoon (*labis*).

THE LITURGICAL CYCLES

Variety of hymnodical texts

One of the major characteristics of the Byzantine liturgical tradition is the wealth and variety of hymnodical texts marking the various cycles of the liturgical year. A special liturgical book contains the hymns for each of the main cycles. The *daily* cycle includes the offices of Hesperinos (Vespers), Apodeipnon (Compline), the midnight prayer, Orthros (Matins), and the four canonical "hours"—*i.e.,* offices to be said at the "First" (6:00 AM), "Third" (9:00 AM), "Sixth" (12:00 noon), and "Ninth" (3:00 PM) hours. The liturgical book covering the daily cycle is called the *Hōrologion* ("The Book of Hours"). The *Paschal* (Easter) cycle is centred on the "Feast of Feasts"—*i.e.,* of Christ's Resurrection; it includes the period of Great Fast (Lent), preceded by three Sundays of preparation and the period of 50 days following Easter. The hymns of the Lenten period are found in the *Triōdion* (Three Odes), and those of the Easter season in the *Pentēkostarion* (called the "Flowery Triodion"). The weekly cycle is the continuation of the Resurrection cycle found in the *Triōdion* and the *Pentēkostarion;* each week following the Sunday after Pentecost (50 days after Easter) possesses its own musical tone, or mode, in accordance with which all the hymns of the week are sung. There are eight tones whose composition is traditionally attributed to St. John of Damascus (8th century). Each week is centred around Sunday, the day of Christ's Resurrection.

The Easter and weekly cycles clearly dominate all offices of the entire year and illustrate the absolute centrality of the Resurrection in the Eastern understanding of the Christian message. The date of Easter, set at the Council of Nicaea (325), is the first Sunday after the full moon following the spring equinox. Differences between the East and West in computing the date exist because the Orthodox Church uses the Julian calendar for establishing the date of the equinox (hence a delay of 13 days) and also because of the tradition that Easter must necessarily follow the Jewish Passover and must never precede it or coincide with it. The *yearly* cycle includes the hymns for each of the 366 days of the calendar year, with its feasts and daily commemoration of saints. They are found in the 12 volumes of the *Menaion* ("Book of Months").

The golden age of Byzantine hymnody

From the 6th to the 9th century the Byzantine Church experienced its golden age of creativity in the writing of hymns by outstanding poets such as John of Damascus. In more recent times hymn writing has generally followed the accepted patterns set by these authors but rarely has it reached the quality of its models. Since the Eastern Orthodox tradition bans instrumental music, or accompaniment, the singing is always a cappella, with only a few exceptions admitted by Westernized parishes in America. The idea behind the ban is based upon the practice of

worship in the New Testament; *i.e.*, only the natural aptitudes of the living congregation are viewed as capable of expressing praise that is worthy of God. In many Orthodox churches there is a wealth of new musical compositions for liturgical texts.

THE SACRAMENTS

Contemporary Orthodox catechisms and textbooks all affirm that the church recognizes seven *mystēria*, or "sacraments": Baptism, chrismation, Communion, holy orders, penance, anointing of the sick (the "extreme unction" of the medieval West), and marriage. Neither the liturgical book called *Euchologion* (prayer book), which contains the texts of the sacraments, nor the patristic tradition, however, formally limits the *number* of sacraments; they do not distinguish clearly between the "sacraments" and such acts as the blessing of water on Epiphany day or the burial service or the service for the tonsuring of a monk that in the West are called *sacramentalia*. In fact, no council recognized by the Orthodox Church ever defined the number of sacraments; it is only through the "Orthodox confessions" of the 17th century directed against the Reformation that the number seven has been generally accepted. The underlying sacramental theology of the Orthodox Church is based, however, on the notion that the ecclesiastical community is the unique *mystērion*, of which the various sacraments or *sacramentalia* are the normal expressions.

The Christian community as the *mystērion*

In the West, since the Scholastic period (Middle Ages) and, especially, since the Catholic Reformation (16th century), much emphasis has been placed on the vicarious juridical power of the minister to administer the sacraments validly. The Orthodox East, however, interprets each sacramental act as a prayer of the entire ecclesiastical community, led by the bishop or his representative, and also as a response of God, based upon Christ's promise to send the Holy Spirit upon the church. These two aspects of the sacrament exclude both magic and legalism: they imply that the Holy Spirit is given to free men and call for their responses. In the *mystērion* of the church, the participation of men in God is effected through their "cooperation" or "synergy"; to make this participation possible once more is the goal of the incarnation.

Baptism and confirmation. Baptism is normally performed by triple immersion as a sign of the death and Resurrection of Christ; thus, the rite appears essentially as a gift of new life. It is immediately followed by confirmation, performed by the priest who anoints the newly baptized Christian with "Holy Chrism" (oil) blessed by the bishop. Baptized and confirmed children are admitted to Holy Communion. By admitting children immediately after their Baptism to both confirmation and Communion, the Eastern Christian tradition maintains the positive meaning of Baptism—*i.e.*, as the beginning of a new life nourished by the Eucharist.

The Eucharist. There never has been, in the East, much speculation about the nature of the eucharistic mystery. Both canons presently in use (that of St. Basil and that of St. John Chrysostom) include the "words of institution" ("This is my Body . . .," "This is my Blood . . ."), which are traditionally considered in the West as the formula necessary for the validity of the sacrament. In the East, however, the culminating point of the prayer is not in the remembrance of Christ's act but in the invocation of the Holy Spirit, which immediately follows: "Send down Thy Holy Spirit upon us and upon the Gifts here spread forth, and make this bread to be the precious Body of Thy Christ. . . ." Thus, the central mystery of Christianity is seen as being performed by the prayer of the church and through an invocation of the Spirit. The nature of the mystery that occurs in the bread and wine is signified by the term *metabolē* ("sacramental change"). The Western term transubstantiation occurs only in some confessions of faith after the 17th century.

Orders. The Orthodox Church recognizes three major orders: the diaconate, the priesthood, and the episcopate (bishop), as well as the minor orders of the lectorate and the subdiaconate. All the ordinations are performed by a bishop and, normally, during the eucharistic liturgy. The consecration of a bishop requires the participation of at least two or three bishops, as well as an election by a canonical synod.

Penance. The sacrament of penance in the early church was a solemn and public act of reconciliation, through which an excommunicated sinner was readmitted into church membership. Historically it has evolved into a private act of confession through which every Christian's membership in the church is periodically renewed. In the Orthodox Church today there is a certain variety in both the practice and the rite of penance. In the churches of the Balkans and the Middle East, it fell into disuse during the four centuries of Turkish occupation but is gradually being restored today. In Greek-speaking churches only certain priests, especially appointed by the bishop, have the right to hear confessions. In Russia, on the contrary, confessions remained a standard practice that was generally required before communion. General or group confession, introduced by John of Kronshtadt, a Russian spiritual leader of the early 20th century, is also occasionally practiced. The rite of confession in the *Euchologion* retains the form of a prayer, or invocation, said by the priest for the remission of the penitent's sins. In the Slavic ritual a Latin-inspired and juridical form of personal absolution was introduced by Peter Mogila, metropolitan of Kiev (17th century). Confession, in Orthodox practice, is generally viewed as a form of spiritual healing rather than as a tribunal. The relative lack of legalism reflects the Eastern patristic approach to sin—*i.e.*, as an internal passion and as an enslavement. The external sinful acts—which alone can be legally tried—are only manifestations of man's internal disease.

Practice of confession

Anointing of the sick. Anointing of the sick is a form of healing by prayer. In the Greek Church it is performed annually in church for the benefit of the entire congregation on the evening of Holy Wednesday.

Marriage. Marriage is celebrated through a rite of crowning, performed with great solemnity and signifying an eternal union, sacramentally "projected" into the Kingdom of God. Orthodox theology of marriage insists on its sacramental eternity rather than its legal indissolubility. Thus, second marriages, in cases of either widowhood or divorce, are celebrated through a subdued penitential rite, and men who have been married more than once are not admitted to the priesthood. Remarriage after divorce is tolerated on the basis of the possibility that the sacrament of marriage was not originally received with the consciousness and responsibility that would have made it fully effective; according to this view, remarriage can be a second chance.

ARCHITECTURE AND ICONOGRAPHY

Since the time of Constantine I, Eastern Christianity has developed a variety of patterns in church architecture. The chief model was created when Emperor Justinian I completed the "great church" of Hagia Sophia in Constantinople in the 6th century. The architectural conception of that church consisted of erecting a huge round dome on top of the classical early Christian basilica. The dome was meant to symbolize the descent of heaven upon earth—*i.e.*, the ultimate meaning of the eucharistic celebration.

The screen, or iconostasis, which separates the sanctuary from the nave in contemporary Orthodox Churches, is a rather late development. After the triumph of orthodoxy over iconoclasm (destruction of images) in 843, a new emphasis was placed upon the permanent revelatory role of *images*. The incarnation implied that God had become man—*i.e.*, fully visible and thus describable in his human nature. The images of Christ and the saints, who had manifested in their lives the new humanity transfigured by the grace of God, were placed everywhere in full evidence before the congregation. A contrast was thus suggested between the visible manifestation of God through the pictural representation of Christ as man and his more perfect but mysterious and invisible presence in the Eucharist. The iconostasis, together with those parts of the liturgy that involve the closing and opening of the curtain before the altar, emphasizes the mysterious and "eschatological" (consummation of history) character of the eucharistic

The Iconoclastic Controversy

service. They suggest, however, that this *mystery* is not a "secret" and that the Christian is being introduced through the eucharistic liturgy into the very reality of divine life and of the kingdom to come, which was revealed when God became man.

The long Iconoclastic Controversy (725–843), during which the Orthodox theology of icons was fully developed, concerned itself primarily with the problem of the incarnation; it was the direct continuation of the Christological debates of the 5th, 6th, and 7th centuries. The image of Christ, the incarnated God, became, for the Eastern Christian, a pictorial confession of faith: God was truly visible in the humanity of Jesus of Nazareth, and the saints—whose images surround that of Christ—are witnesses of the fact that the transfigured, "deified" humanity is accessible to those who believe in Christ.

Popular use of icons

Departing from tridimensional images or statues, which were reminiscent of pagan idolatry, the Christian East developed a rich tradition of iconography. Portable icons—often painted on wood but also using mosaics with enamel techniques—are always kept in houses or public places. Among the icon painters, who never signed their work, there appeared several artists of genius. Most of them are unknown, but tradition and written documents have revealed the names of some, such as the famous 14th–15th-century Russian painter Andrey Rublyov.

The church and the world

The schism between the Greek and the Latin churches coincided chronologically with a surge of Christian missionary activity in northern and eastern Europe. Both sides contributed to the resultant expansion of Christianity but used different methods. The West imposed a Latin liturgy on the new converts and thus made Latin the only vehicle of Christian civilization and a major instrument of ecclesiastical unity. The East, meanwhile, as noted above, accepted from the start the principle of translating both the Scriptures and the liturgy into the spoken tongues of the converted nations. Christianity thus became integrated into the indigenous cultures of the Slavic nations, and the universal Orthodox Church evolved as a fellowship of national churches rather than as a centralized body.

MISSIONS: ANCIENT AND MODERN

The Christian East, in spite of the integrating forces of Christian Hellenism, was always culturally pluralistic: since the first centuries of Christianity, Syrians, Armenians, Georgians, Copts, Ethiopians, and other ethnic groups used their own languages in worship and developed their own liturgical traditions. Even though by the time of the Greek missions to the Slavs the Byzantine Church was almost monolithically Greek, the idea of a liturgy in the vernacular was still quite alive, as is demonstrated by the use of the Slavic language by the missionaries of SS. Cyril and Methodius in the 9th century.

The Turkish conquest of the Middle East and of the Balkans (15th century) interrupted the missionary expansion of the Orthodox Church. Throughout the Middle Ages, Islām and Christianity had usually confronted each other only militarily, and the victory of Islām meant that the Christians could survive only in enclaves and were legally excluded from proselytizing among Muslims.

Russian missionary activity

The Russian Church alone was able to continue the tradition of SS. Cyril and Methodius, and it did so almost without interruption until the modern period. In the 14th century St. Stephen of Perm translated the Scriptures and the liturgy into the language of a Finnish tribe of the Russian north and became the first bishop of the Zyrians. The expansion of the Russian Empire in Asia was accompanied by efforts of evangelization that—sometimes in opposition to the avowed policy of Russianization practiced by the government of St. Petersburg—followed the Cyrillo-Methodian pattern of translation. This method was utilized among the Tatars of the Volga in the 16th century and among the various peoples of Siberia throughout the 18th and the 19th centuries. In 1714 a mission was established in China. In 1794 monks of the Valamo Abbey reached Alaska; their spiritual leader, the monk Herman, was canonized by the Orthodox Church in 1970. Missions in the Islāmic sphere resumed to the extent that by the year 1903 the liturgy was celebrated in more than 20 languages in the region of Kazan.

The Alaskan mission was under the direction of a modest priest sent to America from eastern Siberia, Ivan Veniaminov. During his long stay in America, first as a priest, then as a bishop (1824–68), he engaged in the work of translating the Gospels and the liturgy into the languages of the Aleuts, the Tlingit Indians, and the Eskimos of Alaska.

In Japan an Orthodox Church was established by the recently canonized St. Nikolay Kasatkin (died 1913). The distinctively Japanese character of this church enabled it to survive the political trials of the Russo-Japanese War (1904–05), of the Russian Revolution, and of World War II. The new Church of Japan received its full autonomy from the Russian Church in 1970.

The missionary tradition is also being revived in Greece.

Various Greek associations are dedicated to the pursuit of missionary work in East Africa, where sizable indigenous groups have recently joined the Orthodox Church.

ORTHODOXY AND OTHER CHRISTIANS

Since the failure of the unionist Council of Florence (1439) there have been no official attempts to restore unity between the Orthodox Church and Roman Catholicism. In 1484 an Orthodox council defined that Roman Catholics desiring to join the Orthodox Church were to be received through chrismation (or confirmation). In the 17th century, however, the relations deteriorated to the point that the ecumenical patriarchate of Constantinople decreed that all Roman Catholic and Protestant sacraments, including Baptism, were totally unauthentic. A parallel attitude prevailed in Russia until the 18th century, when large numbers of Eastern Rite Roman Catholics ("Uniates") were received back into Orthodoxy by a simple confession of faith, and this practice was adopted in the acceptance of individual Roman Catholics as well.

After the 16th-century Reformation, a lengthy correspondence took place between the Tübingen group of Reformers (German Lutheran) headed by P. Melanchthon and ecumenical Patriarch Jeremias II. It led to no concrete results, for the East generally considered the Protestants as only a branch of deviation of the altogether erroneous Roman Church.

Various attempts at rapprochement with the Anglican Communion, especially since the 19th century, were generally more fruitful. Several private associations of churchmen and theologians promoted understanding between Eastern Orthodoxy and the "Anglo-Catholic" branch of Anglicanism. The Orthodox, however, were reticent in taking any formal step toward reunion before a satisfactory statement on the content of Anglican faith, taken as a whole, could be obtained.

Ecumenical movement

The contemporary ecumenical movement involved the Orthodox Church from the very beginning. Eastern Orthodox representatives took part in the various Life and Work (practical) and Faith and Order (theological) Conferences from the very beginning of this century. One by one the various independent Orthodox Churches joined the World Council of Churches, created in 1948. Often, and especially at the beginning of their participation, Orthodox delegates had recourse to separate statements, which made clear to the Protestant majorities that, in the Orthodox view, Christian unity was attainable only in the full unity of the primitive apostolic faith from which the Orthodox Church had never departed. This attitude of the Orthodox could be understood only if it made sufficiently clear that the truth—which historic Eastern Orthodoxy claims to preserve—is maintained by the Holy Spirit in the church as a whole and not by any individual or any group of individuals on their own right and also that the unity of Christians—which is the goal of the ecumenical movement—does not imply cultural, intellectual, or ritual uniformity but rather a mystical fellowship in the fullness of truth as expressed in eucharistic Communion.

The ecumenical movement, especially since the second Vatican Council, is today much wider than the formal membership of the World Council of Churches. The principle of conciliarism and the readiness of the popes to appear publicly as equals of Eastern patriarchs—as in the meetings between Pope Paul VI and Patriarch Athenagoras in the 1960s—represent significant moves in the direction of a better understanding between Orthodoxy and Roman Catholicism.

The tendency, however, represented by those Western Christians who apparently identify Christianity with various political or social causes has the effect of again widening the traditional gap that has been, in the past, one of the major causes of the break between East and West.

CHURCH, STATE, AND SOCIETY

In the West, after the fall of the Roman Empire, the church assumed the unifying social function that no other individual or institution was able to fulfill. Eventually, the popes were formally invested with civil authority in Christendom. In the East the empire persisted until 1453 and in Russia until 1917; thus the church had to fulfill its social functions in the political framework of the Christian empire.

This historical contrast coincides with a theological polarization: the Eastern Fathers conceived the God–man relationship in terms of personal experience and Communion culminating in deification; Western theology, meanwhile, understood man as autonomous in the secular sphere, although controlled by the authority of the church, which was conceived as vicariously representing God.

Caesaropapism

The Byzantine and Eastern form of church–state relations has often been labelled as caesaropapism, because the hierarchy of the church was, most of the time, deprived of the legal possibility of opposing imperial power. But this label is inaccurate in two aspects: first, it presupposes that the emperor possessed a recognizable power to define the content of the faith, comparable to that of the papacy; and, second, it underestimates the power of the church (as a corporate, transfiguring, and deifying power) that is effective without legal guarantees or statutes. The Byzantine ideal of church–state relations was a "symphony" between the civil and the ecclesiastical functions of Christian society. The abuses of imperial power were frequent, but innumerable examples of popular resistance to those imperial decrees that were considered as detrimental to the faith can be cited. Neither the strong emperors of the 7th century, trying to impose Monophysitism, nor the weakened Palaeologans (13th to 15th century), attempting reunion with Rome, were able to overcome the corporate opposition of Orthodox clergy and laity.

The Byzantine conception of church–state relations was not, however, without major weaknesses. It often led to a de facto identification of the interests of the church with those of the empire. Conceived when both the church and the empire were supranational and, in principle, universal, it gradually evolved into a system that gave a sacred sanction to *national* states. Modern ecclesiastical nationalism, which inhibits relations between Orthodox Churches today, is the outcome of the medieval alliance between the empire and the church.

Only after the Turkish occupation of the Balkans was civil authority directly assumed by the Orthodox Church hierarchy in the Middle East. It was granted to it by the new Muslim overlords, who chose to administer their Christian subjects as a separate community, or *millet*, ruled by its own religious leaders. The patriarch of Constantinople was thus appointed by the sultan as head (*millet-bachi*) of the entire Christian population of the Ottoman Empire.

The *millet* system of the Ottoman Empire

Understood by some, especially the Greeks, as the heir of Byzantine emperors and by others, especially the Balkan Slavs and Romanians, as an agent of the hated Turks, the patriarch exercised these powers until the secularization of the Turkish republic by Kemal Atatürk in 1921. By that time, however, he had lost most of his jurisdictional powers because of the establishment of autocephalous churches in Greece, Serbia, Bulgaria, and Romania.

The *millet* system, however, survived in other areas of the Middle East. In Cyprus, for example, the church assumed a leading role in national liberation, and its prestige made Archbishop Makarios the natural leader of the young republic.

The *millet* system and the active political responsibilities that it implied for the church, it should be noted, originated in the Ottoman period only and is not in the spiritual tradition of the Christian East as such. The Russian Church is the most recent example of religious survival without practical social or political involvement.

The Orthodox attitude toward social responsibility in the world constitutes a distinct contribution to the contemporary ecumenical movement. But it will be meaningful only if it is understood in its proper framework—*i.e.*, as an understanding of the Christian faith as a personal spiritual experience of God, which is self-sufficient knowledge of God and which, as such, can lead to an authentically Christian witness in the secularized world.

The practical forms of that witness have varied greatly in history, and Orthodox tradition has placed among the church's saints both hermits and politicians, hesychast monks as well as emperors. According to Serge Bulgakov,

a modern Orthodox theologian, the Orthodox Church accepts "a relativism of means and methods," provided there remains "an absolute and unique goal," which is the Kingdom of God still *to come* but also already *present* in the mystery of the church.

Codification and systematization of practical devices in the fields of personal or social ethics is foreign to Orthodoxy, which rather relies on free human conscience; each Christian, in his behaviour, stands before the judgment of the New Testament and of the great examples of the saints. (J.M.)

General: Introductory surveys of the history and doctrines of Eastern Orthodoxy may be found in ERNST BENZ, *The Eastern Orthodox Church, Its Thought and Life* (1963; originally published in German, 1957); TIMOTHY WARE (KALLISTOS WARE), *The Orthodox Church* (1963, reprinted with revisions, 1984); JOHN MEYENDORFF, *The Orthodox Church: Its Past and Its Role in the World Today,* 3rd rev. ed. (1981; originally published in French, 1960), with special attention given to 19th- and 20th-century history; and DEMETRIOS J. CONSTANTELOS, *Understanding the Greek Orthodox Church: Its Faith, History, and Practice* (1982).

History: Overviews of the history of the Eastern Orthodox church are provided by NICOLAS ZERNOV, *Eastern Christendom: A Study of the Origin and Development of the Eastern Orthodox Church* (1961); ALEXANDER SCHMEMANN, *The Historical Road of Eastern Orthodoxy* (1963, reprinted 1977; originally published in Russian, 1954); and JOHN MEYENDORFF, *The Byzantine Legacy in the Orthodox Church* (1982). The best special account of the church in Byzantium until 1261 is found in GEORGE EVERY, *The Byzantine Patriarchate, 451–1204,* 2nd ed. rev. (1962, reprinted 1980). Other works on Byzantine Orthodoxy include STEVEN RUNCIMAN, *The Byzantine Theocracy* (1977), on the relationship between church and state; and J.M. HUSSEY, *The Orthodox Church in the Byzantine Empire* (1986). On the schism between Orthodoxy and Rome, STEVEN RUNCIMAN, *The Eastern Schism* (1955, reprinted 1983); and YVES CONGAR, *After Nine Hundred Years: The Background of the Schism Between the Eastern and Western Churches* (1959, reprinted 1978), are useful. STEVEN RUNCIMAN, *The Great Church in Captivity: A Study of the Patriarchate of Constantinople from the Eve of the Turkish Conquest to the Greek War of Independence* (1968, reissued 1985), critically evaluates the Greek struggle for survival in the Ottoman Empire.

The history of the Orthodox church in Russia is told in VALERI LOBACHEV and VLADIMIR PRAVOTOROV, *A Millennium of Russian Orthodoxy* (1988); GEORGE P. FEDOTOV, *The Russian Religious Mind,* 2 vol. (1946–66, reissued 1975), the best general account of Russian medieval Christianity; DIMITRY POSPIELOVSKY, *The Russian Church Under the Soviet Regime, 1917–1982,* 2 vol. (1984), with a comprehensive bibliography; WILLIAM B. STROYEN, *Communist Russia and the Russian Orthodox Church, 1943–1962* (1967), a sociological analysis; and JANE ELLIS, *The Russian Orthodox Church: A Contemporary History* (1986), from the mid-1960s to the mid-1980s.

Doctrine and sacraments: Doctrinal aspects of the Eastern Orthodox church are detailed by SERGE BULGAKOV, *The Orthodox Church* (1935, reissued 1988; originally published in French, 1932); and VLADIMIR LOSSKY, *The Mystical Theology of the Eastern Church* (1957, reprinted 1976; originally published in French, 1944), a classic on God–man relations, and *Orthodox Theology: An Introduction* (1978). The evolution of Orthodox theology in the Byzantine period is described in JAROSLAV PELIKAN, *The Christian Tradition: A History of the Development of Doctrine,* vol. 2, *The Spirit of Eastern Christendom (600–1700)* (1975); and JOHN MEYENDORFF, *Byzantine Theology: Historical Trends and Doctrinal Themes,* 2nd ed. (1979). GEORGE A. MALONEY, *A History of Orthodox Theology Since 1453* (1976), covers developments since the fall of Constantinople to the Turks in five Orthodox traditions: Russian, Greek, Serbian, Bulgarian, and Romanian. ARTHUR CARL PIEPKORN, *Profiles in Belief: The Religious Bodies of the United States and Canada,* vol. 1, *Roman Catholic, Old Catholic, Eastern Orthodox* (1977), is written for the layperson.

ALEXANDER SCHMEMANN, *For the Life of the World: Sacraments and Orthodoxy,* 2nd rev. and expanded ed. (1973, reissued 1982), is the basic approach to liturgy and sacraments. LEONID OUSPENSKY and VLADIMIR LOSSKY, *The Meaning of Icons,* 2nd ed. (1982; originally published in German, 1952), interprets the icon in its theological and liturgical contexts.

The church and the world: Ancient and modern missions are described by FRANCIS DVORNIK, *Byzantine Missions Among the Slavs: SS. Constantine-Cyril and Methodius* (1970); SERGE BOLSHAKOFF, *The Foreign Missions of the Russian Orthodox Church* (1943); and CONSTANCE J. TARASAR (ed.), *Orthodox America, 1794–1976: Development of the Orthodox Church in America* (1975).

Differences between Orthodoxy and two other Christian denominations are summarized in JOHN MEYENDORFF, *Orthodoxy and Catholicity* (1966; originally published in French, 1965); and CARNEGIE SAMUEL CALIAN, *Icon and Pulpit: The Protestant-Orthodox Encounter* (1968).

Analyses of the relationship between the Eastern Orthodox Church and the state can be found in CHARLES A. FRAZEE, *The Orthodox Church and Independent Greece, 1821–1852* (1969), which uses contemporary diplomatic archives to describe the role of the Greek Church in an event that also involved all major European powers; STEVEN RUNCIMAN, *The Orthodox Churches and the Secular State* (1971), covering the period from the Byzantine Empire to the contemporary situations under Communism, Islām, and dictators; and PEDRO RAMET (ed.), *Eastern Christianity and Politics in the Twentieth Century* (1988). (Ed.)

Echinoderms

Echinodermata is a phylum of marine invertebrate animals whose living representatives include the classes Crinoidea (sea lilies and feather stars), Echinoidea (sea urchins), Holothuroidea (sea cucumbers), Asteroidea (starfishes, or sea stars), Ophiuroidea (basket stars and serpent stars, or brittle stars), and the recently discovered Concentricycloidea (sea daisies). Beginning with the Lower Cambrian Period almost 570,000,000 years ago, echinoderms have a rich fossil history and are well represented by many bizarre groups, most of which are now extinct.

Echinoderms have been recognized since ancient times; echinoids, for example, were used extensively by Greeks and Romans for medicinal purposes and as food. During the Middle Ages, fossil echinoids and parts of fossil crinoids were objects of superstition. In the early part of the 19th century, Echinodermata was recognized as a distinct group of animals and was occasionally associated with the cnidarians and selected other phyla in a division of the animal kingdom known as the Radiata; the concept of a superphylum called Radiata is no longer valid. Echinoderms now may be separated into 21 classes, based mainly on differences in skeletal structures. The number of extant species exceeds 6,000, and approximately 13,000 fossil species have been described.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 313, and the *Index*.

This article is divided into the following sections:

GENERAL FEATURES

Size range and diversity of structure. Although most echinoderms are of small size, ranging up to 10 centimetres (four inches) in length or diameter, some reach relatively large sizes; *e.g.*, some sea cucumbers are as long as two metres (about 6.6 feet), and a few starfishes have a diameter of up to one metre. Among the largest echinoderms were some extinct (fossil) crinoids (sea lilies), whose stems exceeded 20 metres in length.

Echinoderms exhibit a great diversity of body forms, especially among the extinct groups. Although all living echinoderms have a pentamerous (five-part) radial symmetry, an internal skeleton, and a water-vascular system derived from the coelom (central cavity), their general appearance ranges from that of the stemmed, flowerlike sea lilies, to the wormlike, burrowing sea cucumbers, to the heavily armoured intertidal starfish or sea urchin (see Figure 1). The general shape of the echinoderm may be that of a star with arms extended from a central disk or with branched and feathery arms extended from a body often attached to a stalk, or it may be round to cylindrical. Plates of the internal skeleton may articulate with each other (as in sea stars) or be sutured together to form a rigid test (sea urchins). Projections from the skeleton, sometimes resembling spikes, which are typical of echinoderms, give the phylum its name (from Greek *echinos*, "spiny," and *derma*, "skin"). The surface of holothurians, however, is merely warty.

Colour range

Echinoderms also exhibit especially brilliant colours such as reds, oranges, greens, and purples. Many tropical species are dark brown to black, but lighter colours, particularly yellows, are common among species not normally exposed to strong sunlight.

Distribution and abundance. Diverse echinoderm faunas consisting of many individuals and many species are found in all marine waters of the world except the Arctic, where few species occur. Echinoids, including globular spiny urchins and flattened sand dollars, and asteroids are commonly found along the seashore. Although many species are restricted to specific temperate regions, Arctic, Antarctic, and tropical forms often are widely distributed; many species associated with coral reefs, for example, range across the entire Indian and Pacific oceans. Many of the echinoderms of Antarctica are distributed around the continent; those with a floating (planktonic) larval stage may be widely distributed, carried great distances by ocean currents. Some species, particularly those in Antarctic and deep-sea regions, have achieved a wide distribution without benefit of a floating larval stage. They may have done so by migration of adults across the seafloor or, in the case of shallow-water species, by passive transport across oceans in rafts of seaweed. Echinoderms tend to have a fairly limited depth range; species occurring in near-shore environments do not normally reach depths greater than 100 metres. Some deep-sea species may be found over a considerable range of depths, often from 1,000 metres to more than 5,000 metres. One sea cucumber species has a known range of 37–5,205 metres. Only sea cucumbers reach ocean depths of 10,000 metres and more.

Depth range

Importance. *Role in nature.* Echinoderms are efficient scavengers of decaying matter on the seafloor, and they prey upon a variety of small organisms, thereby helping to regulate their numbers. When present in large numbers, sea urchins can devastate sea-grass beds in the tropics, adversely affecting the organisms dwelling within. Sea urchins that burrow into rocks and along a shore can accelerate the erosion of shorelines. Other tropical species of sea urchins, however, control the growth of seaweeds in coral reefs, thereby permitting the corals to flourish. Removal of the sea urchins results in the overgrowth of seaweeds and the devastation of the coral reef habitat. Echinoderms can alter the structure of seafloor sediments in a variety of ways. Many sea cucumbers feed by swallowing large quantities of sediment, extracting organic matter as the sediment passes through the intestine, and ejecting the remainder. Large populations of sea cucumbers in an area can turn over vast quantities of surface sediments and can greatly alter the physical and chemical composition of the sediments. Burrowing starfish, sand dollars, and heart urchins disturb surface and subsurface sediments, sometimes to depths of 30 centimetres or more. In addition, echinoderms produce vast numbers of larvae that provide food for other planktonic organisms.

Relation to human life. Some of the larger species of

The stalk attaches to a hard substrate. (Top centre right) Holothurian (*Euapta lappa*), which has a soft body, with 10 or more feeding tentacles around the mouth. (Top right) Brittle star (*Ophiomyxa flaccida*) with long slender arms. (Bottom left) An irregular echinoid (*Linopneustes longispinus*). (Bottom centre) A regular echinoid (*Eucidaris tribuloides*) with spines and test with five-part symmetry. (Bottom right) Asteroid (*Astropecten nitidus*), showing typical five-part symmetry.
John E. Miller

tropical sea cucumbers, known commercially as trepang or bêche-de-mer, are dried and used in soups, particularly in Asia. Raw or cooked mature sex organs, or gonads, of sea urchins are regarded as a delicacy in some parts of the world, including parts of Europe, the Mediterranean region, Japan, and Chile. Some tropical holothurians produce a toxin, known as holothurin, which is lethal to many kinds of animals; Pacific islanders kill fish by poisoning waters with holothurian body tissues that release the toxin. Holothurin does not appear to harm human beings; in fact, the toxin has been found to reduce the rate of growth of certain types of tumours and thus may have medical significance. The eggs and spermatozoa of echinoderms, particularly those of sea urchins and starfishes, are easily obtained and have been used to conduct research in developmental biology. Indeed, echinoids have been collected in such large numbers that they have become rare or have disappeared altogether from the vicinity of several marine biologic laboratories.

Holothurin toxin

Starfishes that prey upon commercially usable mollusks, such as oysters, have caused extensive destruction of oyster beds. Sea urchins along the California coast have interfered with the regrowth of commercial species of seaweed by eating the young plants before they could become firmly established. The crown-of-thorns starfish, which feeds on living polyps of reef corals, has caused extensive short-term damage to coral reefs in some parts of the Pacific and Indian oceans.

NATURAL HISTORY

Reproduction and life cycle. In most species the sexes are separate; *i.e.*, there are males and females. Although reproduction is usually sexual, involving fertilization of eggs by spermatozoa, several species of sea cucumbers, starfishes, and brittle stars can also reproduce asexually.

Asexual reproduction. Asexual reproduction in echinoderms usually involves the division of the body into two or more parts (fission) and the regeneration of missing body parts. Fission is a common method of reproduction in approximately 60 species of asteroids, ophiuroids, and holothurians (a total of less than 1 percent of the living species), and in some of these species sexual reproduction is not known to occur. Successful fission and regeneration require a body wall that can be torn and an ability to seal resultant wounds. In some asteroids fission occurs when two groups of arms pull in opposite directions, thereby tearing the animal into two pieces. Successful regeneration requires that certain body parts be present in the lost pieces; for example, many asteroids and ophiuroids can regenerate a lost portion only if some part of the disk is present. In sea cucumbers, which divide transversely, considerable reorganization of tissues occurs in both regenerating parts.

Fission and regeneration

The ability to regenerate, or regrow, lost or destroyed parts is well developed in echinoderms, especially sea lilies, starfishes, and brittle stars, all of which can regenerate new arms if existing ones are broken off. Echinoderm regeneration frustrated early attempts to keep starfishes from destroying oyster beds; when captured starfishes were chopped into pieces and thrown back into the sea, they actually increased in numbers. So long as a portion of a body, or disk, remained associated with an arm, new starfishes regenerated. Some sea cucumbers can expel their internal organs (autoeviscerate) under certain conditions (*i.e.*, if attacked, if the environment is unfavourable, or on a seasonal basis), and a new set of internal organs regenerates within several weeks. Sea urchins (Echinoidea) readily regenerate lost spines, pincerlike organs called pedicellariae, and small areas of the internal skeleton, or test.

Sexual reproduction. In sexual reproduction, eggs (up to several million) from females and spermatozoa from males are shed into the water (spawning), where the eggs are fertilized. Most echinoderms spawn on an annual cycle, with the spawning period normally lasting one or two months during spring or summer; several species, however, are capable of spawning throughout the year. Spawn-inducing factors are complex and may include external influences such as temperature, light, or salinity of the

water. In the case of one Japanese feather star (Crinoidea), spawning is correlated with phases of the Moon and takes place during early October when the Moon is in the first or last quarter. Many echinoderms aggregate before spawning, thus increasing the probability of fertilization of eggs. Some also display a characteristic behaviour during the spawning process; some asteroids and ophiuroids raise the centre of the body off the seafloor; holothurians may raise the front end of the body and wave it about. These movements are presumably intended to prevent eggs and sperm from becoming entrapped in the sediment.

Development. After an egg is fertilized, the development of the resulting embryo into a juvenile echinoderm may proceed in a variety of ways. Small eggs without much yolk develop into free-swimming larvae that become part of the plankton, actively feeding on small organisms until they transform, or metamorphose, into juvenile echinoderms and begin life on the seafloor. Larger eggs with greater amounts of yolk may develop into a larval form that is planktonic but subsists upon its own yolk material, rather than feeding upon small organisms, before eventually transforming into a juvenile echinoderm. Development involving an egg, planktonic larval stages, and a juvenile form is termed indirect development. Echinoderm development in which large eggs with abundant yolk transform into juvenile echinoderms without passing through a larval stage is termed direct development.

Brooding

In direct development the young usually are reared by the female parent. Parental care or brood protection ranges from actual retention of young inside the body of the female until they are born as juveniles to retention of the young on the outer surface of the body. Brood protection is best developed among Antarctic, Arctic, and deep-sea echinoderms, in which young may be held around the mouth or on the underside of the parent's body, as in some starfishes and sea cucumbers, or in special pouches on the upper surface of the body, as in some sea urchins, sea cucumbers, and asteroids.

During indirect development, the fertilized egg divides many times to produce a hollow ciliated ball of cells (blastula); cleavage is total, indeterminate, and radical. The blastula invaginates at one end to form a primitive gut, and the cells continue to divide to form a double-layered embryo called the gastrula. Echinoderms resemble vertebrates and some invertebrate groups (chaetognaths and hemichordates) in being deuterostomes; the hole through which the gut opens to the outside (blastopore) marks the position of the future anus; the mouth arises anew at the opposite end of the body from the blastopore. A pair of subdivided hollow pouches arise from the gut and develop into the body cavity (coelom) and water-vascular system.

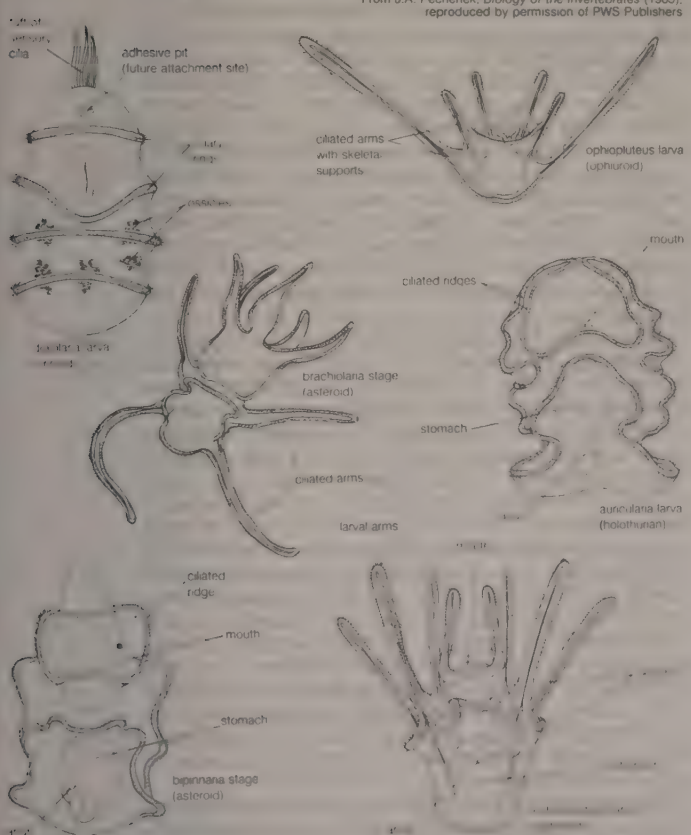

Figure 2: Larval forms of some living classes of echinoderms.

Larval types

The gastrula develops into a basic larval type called a dipleurula larva, characterized by bilateral symmetry; hence the name, which means "little two sides." A single band of hairlike projections, or cilia, is found on each side of the body and in front of the mouth and anus. The characteristic larvae found among the living classes of echinoderms (Figure 2) are modifications of the basic dipleurula pattern.

Because the ciliated band of the dipleurula larva of holothurians becomes sinuous and lobed, thus resembling a human ear, the larva is known as an auricularia larva. The dipleurula larva of asteroids develops into a bipinnaria larva with two ciliated bands, which also may become sinuous and form lobes or arms; one band lies in front of the mouth, the other behind it and around the edge of the body. In most asteroids the larval form in the next stage of development is called a brachiolaria, which has three additional arms used for attaching the larva to the seafloor. Echinoids and ophiuroids have complex advanced larvae closely similar in type. The larva, named pluteus, resembles an artist's easel turned upside down. It has fragile arms formed by lobes of ciliated bands and is supported by fragile rods of calcite, the skeletal material. The echinoid larva (echinopluteus) and the ophiuroid larva (ophiopluteus) usually have four pairs of arms but may have fewer or more. An extra unpaired arm on the plutei of sand dollars and cake urchins extends downward, presumably to help keep the larva upright. The crinoids, which apparently lack a dipleurula larval stage, have a barrel-shaped larva called a doliolaria larva. The doliolaria larva also occurs in other groups; in holothurians, for example, it is the developmental stage after the auricularia larva, which may not occur in some species. A doliolaria larva usually contains large quantities of yolk material and moves with the aid of several ciliated bands arranged in hoops around the body.

Although most larval stages are small, often less than one millimetre (0.04 inch) in length, some holothurians are known to be 15 millimetres long in the larval stage, and the length of bipinnaria larvae of some starfishes may exceed 25 millimetres.

Metamorphosis

After a few days to several weeks in a free-swimming form (plankton), echinoderm larvae undergo a complex transformation, or metamorphosis, that results in the juvenile echinoderm. During metamorphosis, the fundamental bilateral symmetry is overshadowed by a radial symmetry dominated by formation of five water-vascular canals (see below *Form and function: External features*). Among holothurians, echinoids, and ophiuroids, the larvae may metamorphose as they float, and the young then sink to the seafloor; among crinoids and asteroids, however, the larvae firmly attach to the seafloor prior to metamorphosis. The average life span of echinoderms is about four years, and some species may live as long as eight or 10.

Food and feeding habits. Echinoderms feed in a variety of ways. A distinct feeding rhythm frequently occurs, with many forms feeding only at night, others feeding continuously. Feeding habits range from active, selective predation to omnivorous scavenging or nonselective mud swallowing.

Crinoids are suspension feeders, capturing planktonic organisms in a network of mucus produced by soft appendages, called tube feet, contained in grooves on the tentacles, or arms. The arms are spread into a characteristic "fan" at right angles to the prevailing current, and small prey animals are passed to the mouth along the grooves by activity of the cilia and the tube feet.

Many asteroids are active predators on shellfishes and even upon other starfishes; other asteroids are mud swal-

lowers. When feeding, some asteroid species extrude their stomach through the mouth onto the prey, which then is partially digested externally, after which the stomach is retracted and digestion is completed inside the body. Most ophiuroids feed on small organisms floating in the water or lying on the bottom, which are captured by the arms and tube feet and passed toward the mouth. Ophiuroids with arms branched in a complex manner may feed in a way similar to that of the crinoids. Feeding methods of concentricycloids are not yet known.

Regular and irregular echinoids

The more primitive, so-called regular, sea urchins are omnivorous or vegetarian browsers, either scraping algae and other small organisms from rocks with their hard teeth or eating seaweed. Several deep-sea regular echinoids feed exclusively on plants carried into the sea from the land. The more advanced irregular echinoids, which usually lack teeth, are burrowers and pass small organisms to the mouth with the aid of spines and tube feet. Several species of sand dollars sometimes feed on suspended organisms carried to them by ocean currents as they lie on the seafloor. Some sea cucumbers remain attached to a surface for indefinite periods of time, capturing plankton in a network of branching, sticky tentacles; others select food from the seafloor and push it into their mouths with their tentacles. A large number of holothurians feed by actively swallowing mud and sand, digesting the organic material, and egesting the waste in the form of characteristic castings, in a manner similar to that of earthworms.

Under artificial conditions, as in aquariums, echinoderms can survive apparent starvation for several weeks at a time. After a holothurian has autoeviscerated, it is unable to feed during the several weeks required for gut regeneration. Echinoderms may derive a significant amount of nourishment, at least for the outer cell layers of the body, from organic material dissolved in seawater.

Locomotion. Asteroids and echinoids, which use spines and tube feet in locomotion, may move forward with any area of the body and reverse direction without turning around. The feet may be used either as levers, by means of which the echinoderm steps along a surface, or as attachment mechanisms that pull the animal. Sea daisies presumably move in the same way. Ophiuroids tend to move by thrashing the arms in one of several possible methods, including a rowing motion in which strokes are taken by two pairs of extended arms; the fifth arm either is extended forward in the direction in which the animal is traveling or trails behind.

Holothurians (sea cucumbers) generally lead with the mouth, or oral, end, movement being carried out by both the tube feet and contraction and expansion of the body; sluglike movement is common. Holothurians of the family Synaptidae are able to pull themselves across a surface using their sticky tentacles as anchors.

Stalked crinoids (sea lilies), so called because they have stems, generally are firmly fixed to a surface by structures at the ends of the stalks called holdfasts. Some fossil and living forms release themselves to move to new attachment areas. The unstalked crinoids (feather stars) generally swim by thrashing their numerous arms up and down in a coordinated way; for example, in a 10-armed species, when arms 1, 3, 5, 7, and 9 are raised upward, arms 2, 4, 6, 8, and 10 are forcibly pushed downward; then the former group of arms thrashes downward as the latter is raised. Feather stars that do not swim pull themselves across a surface using their arms.

Swimming

Swimming is known to occur in crinoids, ophiuroids, and holothurians. Some holothurians, formerly regarded as strictly bottom-living forms, are capable of efficient swimming; others, with gelatinous or flattened bodies and reduced calcareous skeletons, spend most of their lives swimming in deep water.

Righting response. Among echinoderms a normal position may be with the mouth either facing a surface, as in asteroids, ophiuroids, concentricycloids, and echinoids, or facing away from it, as in crinoids and holothurians. When overturned, echinoderms exhibit a righting response. Starfishes show this response most effectively, using the tube feet and the arms to perform a slow, graceful somersault that restores their normal position. Sea urchins roll themselves over by a concerted action of their tube feet and spines. The flat sand dollar can turn itself over only by burrowing into the sand until its position is vertical, then toppling over. In more agile groups such as holothurians, crinoids, and ophiuroids, righting is performed with relative ease.

Burrowing. Many echinoderms burrow in rock or soft sediments. Crinoids do not burrow because their feeding apparatus must be kept clear of sediment. Some urchins use the combined abrasive actions of their spines and teeth to burrow several inches into rock, usually in areas of severe wave and tidal action. The so-called irregular echinoids excavate soft sediments to various depths; most sand dollars burrow just below the surface, and some heart urchins may be found at depths of 38 centimetres or more. Holothurians use tentacles and contraction of the body wall in burrowing that generally is related to feeding. Several asteroid species bury themselves in sandy or muddy areas. The characteristic position of several ophiuroid groups involves burying the body into a surface and leaving only the tips of the arms projecting for food gathering.

Ecology. *Habitats.* Echinoderms are exclusively marine animals, with only a few species tolerating even brackish water. Among the exceptions are a few tropical holothurians that can withstand partial drying if stranded on a beach by a receding tide. Most echinoderms cannot tolerate marked changes in salinity, temperature, and light intensity and tend to move away from areas where these factors are not optimal. The behaviour of a large proportion of shallow-water species is regulated by light; *i.e.,* individuals remain concealed during the day and emerge from concealment at night for active feeding. Echinoderms are found in the warmest and coldest of the world's seas; those species that can tolerate a broad temperature range usually also have a broad geographic range. The horizontal or vertical distribution of many species is also governed by water temperature. The influence of pressure upon echinoderms has not yet been thoroughly investigated.

Influence of external factors

Echinoderms occupy a variety of habitats. Along a rocky shore, starfishes and sea urchins may cling to rocks beneath which sea cucumbers and brittle stars are concealed. Some sea urchins have special adaptations for coping with surf pounding against rocks (*e.g.,* particularly strong skeletons and well-developed tube feet for attachment). In sandy areas starfishes, brittle stars, irregular sea urchins, and sea cucumbers may bury themselves or move on the surface. Large populations of all living groups of echinoderms can be found in mud and ooze offshore. In some marine areas, echinoderms are the dominant organism; in the deepest ocean trenches, for example, holothurians may constitute more than 90 percent by weight of the living organisms. Perhaps the most unusual habitat is exploited by sea daisies and a small family of asteroids; these animals occur only on pieces of waterlogged wood on the deep-sea floor.

Animal hosts

Echinoderms frequently use other animals as homes; thousands of brittle stars, for example, may live in some tropical sponges. Sea cucumbers may attach themselves to the spines of sluggish Antarctic echinoids, and one sea cucumber attaches itself to the skin of a deep-sea fish. On the other hand, echinoderms are also hosts to a wide variety of organisms. Various crustaceans and barnacles, for example, cause the formation of galls, or tumourlike growths, in the skeletons of sea urchins, and crinoids are hosts of specialized parasitic worms. Commensal worms, which do no damage, are associated with most groups; an interesting case of commensalism is the association between various tropical sea cucumbers and the slender pearlfish, which often is found in the rectum of the holothurian, head protruding through its anus. Pinnotherid crabs may be found in the rectum of echinoids and holothurians in Peru and Chile, and highly modified parasitic gastropod mollusks are frequently found in the body cavities of holothurians. A conspicuous parasitic sponge grows on two species of Antarctic ophiuroids.

Predation and defense. Although echinoderm populations do not generally suffer from heavy predation by other animals, ophiuroids form a significant part of the

diet of various fishes and some asteroids. Echinoids are frequently eaten by sharks, bony fishes, spider crabs, and gastropod mollusks; crows, herring gulls, and eider ducks may either peck their tests (internal skeletons) or drop them repeatedly until they break; and mammals, including the Arctic fox, sea otters, and humans, eat them in considerable numbers. Asteroids are eaten by other asteroids, mollusks, and crustaceans. Some holothurians are eaten by fishes and by humans. Crinoids appear to have no consistent predators.

Defense mechanisms

Echinoderms can protect themselves from predation in a variety of ways, most of which are passive. The presence of a firm skeleton often deters predators; echinoids, for example, have a formidable array of spines and, in some cases, highly poisonous stinging pincerlike organs (pedicellariae), some of which may cause intense pain and fever in humans. Some asteroids use chemical secretions to stimulate violent escape responses in other animals, particularly predatory mollusks. Some holothurians eject from the anus a sticky mass of white threads, known as cuvierian tubules, which may entangle or distract predators; others produce holothurin, a toxin lethal to many would-be predators.

Aggregation. Echinoderms tend to aggregate in large numbers and evidently also did so in the past; fossil beds consisting almost exclusively of large numbers of one or a few species are known from as early as the Lower Cambrian. In present-day seas, ophiuroids may cover large areas of the seafloor; vast aggregations of echinoids are also common. Holothurians, crinoids, and some asteroids also often show a tendency to aggregate.

The phenomenon of aggregation apparently is a response to one or more environmental factors, chief of which is availability of food; *e.g.*, large numbers of ophiuroids and crinoids occupy areas in which strong currents carry large amounts of plankton. An ophiuroid raises some arms into the water to capture food, using other arms to hold on to other nearby ophiuroids; in this way, a large aggregation can maintain its position in an environment in which a single ophiuroid or a small clump of them would be swept away. As stated previously, aggregation also enhances possibilities for successful propagation of a species and possibly may afford some protection from predators. Aggregation may be a passive phenomenon resulting from interactions between individuals and the environment as well as a demonstration of true social behaviour, a result of interactions among individuals.

FORM AND FUNCTION

Coelom

General features. Echinoderms have a skeleton composed of numerous plates of mineral calcium carbonate (calcite). Part of the body cavity, or coelom, is a water-vascular system, consisting of fluid-filled vessels that are pushed out from the body surface as tube feet, papillae, and other structures that are used in locomotion, feeding, respiration, and sensory perception. The conspicuous five-rayed, or pentamerous, radial symmetry of living echinoderms tends to obliterate their fundamental bilateral symmetry.

External features. *Symmetry and body form.* Many of the earliest echinoderms either lacked symmetry or were bilaterally symmetrical. Bilateral symmetry occurs in all living groups and is especially marked in the larval stages. A tendency toward radial symmetry (the arrangement of body parts as rays) developed early in echinoderm evolution and eventually became superimposed upon the fundamental bilateral symmetry, often obliterating it. Radial pentamerous symmetry is conspicuous among all groups of living echinoderms. Although the reasons for the success of radial symmetry are not yet completely understood, it has been suggested that a pentamerous arrangement of skeletal parts strengthens an animal's skeleton more than would, for example, a three-rayed symmetry.

Pentamerous structure is evident in the arrangement of the tube feet, which usually radiate from the mouth in five bands. Many of the major organ systems, including the water-vascular system, muscles, hemal system (a series of fluid-filled spaces of indeterminate function), and parts of the nervous system are also pentamerous. The skeleton follows a pentamerous pattern, except in holothurians, where it is usually reduced to microscopic ossicles (bones).

Growth patterns

Distinct growth patterns among the echinoderms provide some basis for separating the phylum into subphyla. Among homalozoans, the pattern is asymmetrical. In crinozoans and blastozoans, bands of tube feet radiate from the mouth, cross the theca (*i.e.*, sheath or calyx), and extend onto the brachioles or arms; in asterozoans the bands of tube feet radiate outward from the mouth onto the arms to produce a star shape; and in the armless echinozoans, the tube feet form five meridians on the spherical or cylindrical body.

The crinoid (sea lily, feather star) mouth is centrally located on the cup-shaped theca; from which arise a variable number of arms resembling fern fronds. Although five is the primitive number of arms, they branch once or several times in most living forms to produce 10 to 200 arms. Crinoids either are supported on a stem (or stalk) attached to the underside of the theca, or they lack stalks, as is the case with most living forms, and attach themselves by means of slender appendages adapted for grasping (prehensile cirri).

Asteroids have a large central disk from which radiate five or more hollow arms containing parts of the major internal organ systems. The underside (oral surface) of the disk contains a centrally located mouth; the underside of each arm contains five or more bands of tube feet in special grooves called ambulacral furrows. The upper (aboral) surface of the disk has a centrally located anus (often absent) and the sieve plate (madreporite) of the water-vascular system (see below *Internal features: Water-vascular system*). Seven-armed starfish species are not unusual, a deep-sea family has six to 20 arms, and one Antarctic genus may have up to 50 arms. Concentricycloids have a discoid body; the dorsal surface is plated andthe ventral surface is naked (Figure 3).

Ophiuroids have a small disk from which five arms radiate. The larger internal organs usually are confined to the disk. The centrally located mouth is on the underside of the disk as are the tube feet, which are not arranged in special grooves. Although most ophiuroids have five arms, a few have six or more, and in one group, the basket stars, the five arms are branched to form a complex network.

In echinoids (Figure 4) the skeleton forms a rounded,

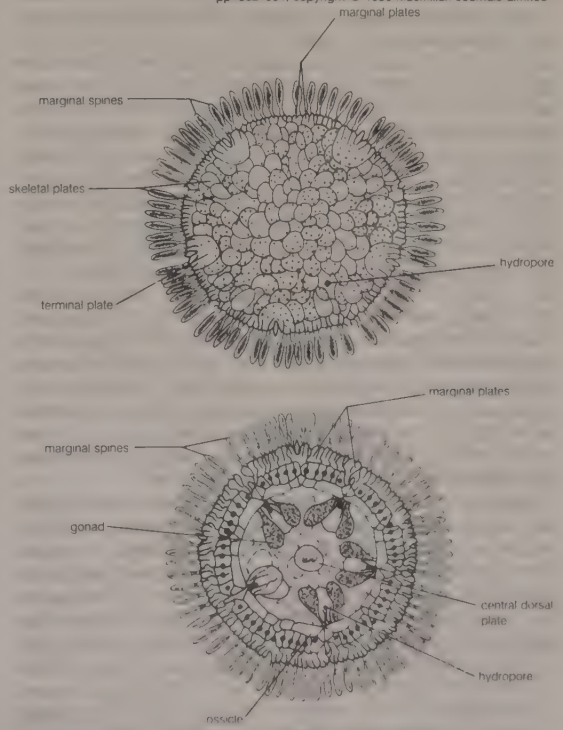

Figure 3: Sea daisy (*Xyloplax medusiformis*) of the class Concentricycloidea. (Top) Dorsal view; (bottom) ventral view.

or globular, test of solid plates; tube feet, which emerge through holes in the plates, form five conspicuous bands, or ambulacra. Spaces between bands of feet are called interambulacra. Regular echinoids are roughly spherical in shape, with a centrally located mouth at the junction of the five bands containing tube feet (ambulacra); the anus is located on the side of the body opposite the mouth (aboral). Irregular urchins are elongated or flattened in shape, with the anus on the oral or aboral surface of the body. In regular and some irregular echinoids, the mouth is equipped with five teeth operated by a complex system of plates and muscles called Aristotle's lantern.

Aristotle's lantern

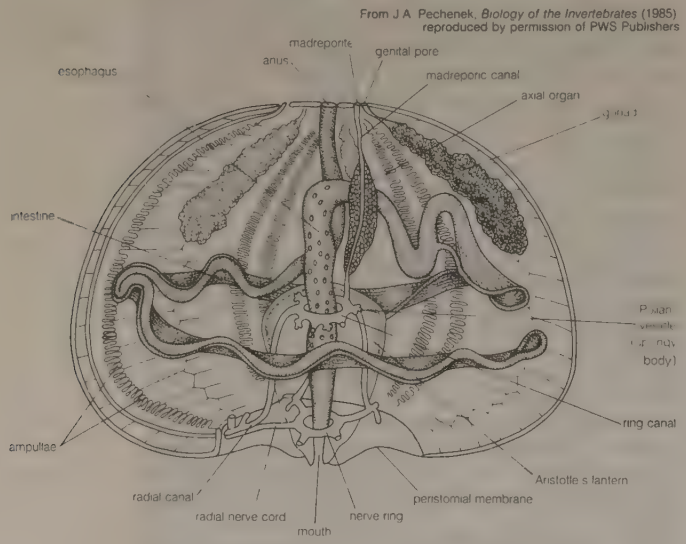

Figure 4: Sea urchin (*Arbacia punctulata*). Internal structures are shown laterally in diagrammatic section.

Holothurians are elongated, with mouth and anus at opposite ends of the body. The spaces between the tube feet, which are arranged in five rows, or radii, are known as interradii. The tube feet may be more numerous on the underside of the body than elsewhere, scattered over radii and interradii, or absent. Most holothurians are soft-bodied animals because the skeleton is reduced and the skeletal units, called ossicles or spicules, are microscopic in size. Holothurians usually show bilateral symmetry outside, radial symmetry inside.

Skeleton. The skeleton is dermal but nonetheless conspicuous in echinoderms, with the exception of most holothurians, and forms an effective armour. Each skeletal unit (ossicle) usually consists of two parts, a living tissue (stroma) and a complex lattice (stereom) of mineral calcium carbonate, or calcite, which is derived from the stroma. In living echinoderms, certain properties of calcite are not evident in the stereom because of its latticed structure and the presence of soft stroma. In fossils, however, the stroma may be replaced by secondary calcite (*i.e.*, calcite laid down in continuity with the original skeletal calcite), and recognition of fragments of echinoderm skeletons in fossil strata is easier because no other animal group has the same type of skeleton. Each ossicle is formed from granules in the dermal layer that, after secretion from special lime-secreting cells, enlarge, branch, and fuse to build up a three-dimensional network of calcite. Parts of the skeleton enlarge as an animal grows, and resorption and regeneration of the skeleton may occur.

Skeletal structures

Echinoderms exhibit a variety of skeletal structures. In the echinoids, a hollow test (skeleton) consisting of 10 columns of plates bears large and small spines as well as pincerlike organs (pedicellariae) used in defense and in the removal of unwanted particles from the body. Pedicellariae, also found in the asteroids, are absent from crinoids, ophiuroids, and holothurians. The complex feeding apparatus (Aristotle's lantern) of echinoids consists of 40 ossicles held together by muscles and collagenous sutures.

Crinoids have a hollow sheath (theca or calyx) composed of two or three whorls, each consisting of five skeletal plates; the stalk and the slender appendages (cirri) of unstalked forms consist of a series of drum-shaped ossicles. The asteroid skeleton is composed of numerous smooth or spine-bearing ossicles of various shapes held together by muscles and ligaments, permitting flexibility. The arms of asteroids are hollow, those of ophiuroids solid, with the central axis of each arm consisting of elongated ossicles called vertebrae. The microscopically sized ossicles of holothurians are highly variable in form, ranging from flat lattice plates with holes to exquisitely symmetrical wheels, and are usually numerous; one tropical species, for example, has more than 26,000,000 ossicles in its body wall. A ring of plates, called the calcareous ring, surrounds the tube leading from the mouth to the stomach (*i.e.*, the esophagus) of holothurians. Although located in a similar position to that of the echinoid Aristotle's lantern, the calcareous ring functions as a point of insertion for muscles, not as a feeding apparatus.

Internal features. *Water-vascular system.* The water-vascular system, which functions in the movement of tube feet, is a characteristic feature of echinoderms, and evidence of its existence has been found in even the oldest fossil forms (Figure 5). It comprises an internal hydraulic system of canals and reservoirs containing a watery fluid, the system consisting of a sieve plate, or madreporite, and a ring vessel, or water-vascular ring, that are connected by a frequently calcified vessel called the stone canal. Five radial water canals extend outward from the ring vessel and give rise to branches that end in the tube feet, which are in contact with the sea. The ring vessel in ophiuroids, asteroids, concentricycloids, and holothurians has bulbous cavities called Polian vesicles, which apparently maintain pressure in the system and hold reserve supplies of fluid; ophiuroids have four or more vesicles, asteroids five, holothurians from one to 50. Crinoids lack Polian vesicles, and echinoids have five structures known as either Polian vesicles or spongy bodies.

Polian vesicles

The madreporite, which is usually located externally, takes in water from outside the body; if internally located, as is the case in many holothurians, fluid is taken from the body cavity. The water or fluid passes from the madreporite to the ring vessel and along the radial canals to the tube feet. The tube feet are extended by contractions of localized muscle areas in the radial canals (ophiuroids) or by contractions of offshoots of the radial canals called ampullae (asteroids, concentricycloids, echinoids, and holothurians); the contractions force fluid into the tube feet, which then extend.

The structure of the system varies from group to group; asteroids frequently have more than one madreporite, and in holothurians, the madreporite is usually internal, hanging in the coelom. Radial canals may lie inward or outward from the skeleton. The tube feet may have well-developed suckers with great holding power, may taper to a point, or may be adapted for respiration, feeding, burrow building, mucus production, or sensory perception. Attachment of tube feet to hard substrates is achieved through a combination of suction and mucus production. The mucus contains adhesive and de-adhesive mucopolysaccharides. Respiratory tube feet have high oxygen uptake; they are usually located on parts of the body where

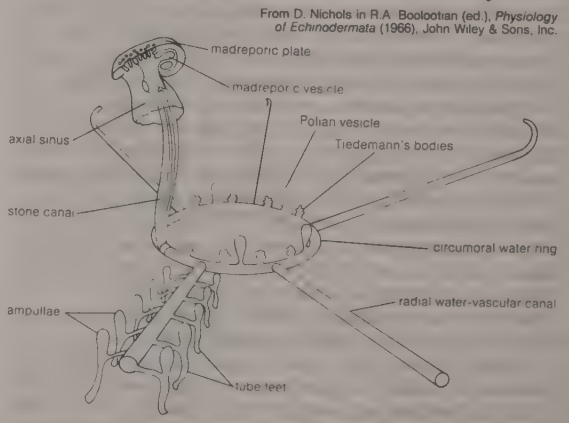

Figure 5: Water-vascular system of an asteroid.

water flow is unimpeded. Tube feet have been implicated in photoreception and chemoreception; the eyespots in the terminal tentacles of asteroids are the most conspicuous photoreceptors.

The tube feet of crinoids are arranged in clumps of three on the arms and on the pinnules. They secrete and spread a net of sticky mucus that traps small organisms. In ophiuroids the tube feet are used to gain a hold on a surface and to pass food to the mouth. The numerous tube feet of asteroids are used in locomotion; asteroids with suckered feet may use them to exert a continuous pull on the valves of shellfish (*e.g.,* oysters, mussels) until muscles holding the valves tire and open slightly, allowing the asteroid to insert its stomach. In sea daisies the ring of tube feet is probably used for attachment to substrates. Holothurians use tube feet for the same purpose. Tentacles around the mouth of holothurians are modified tube feet used to capture food; tentacles used to capture plankton are branched and sticky, while those used to scoop mud and shovel it into the mouth have a simpler structure.

The tube feet of echinoids serve a variety of functions. The mouth of regular echinoids is surrounded by sensory tube feet, and tube feet farther from the mouth are used in locomotion. On the upper side of the body near the anus, the tube feet have respiratory and sensory functions. The tube feet of irregular echinoids, which burrow, are modified in various ways for feeding, burrow construction, and sensory and respiratory functions.

Body wall and body cavity. The outer body wall (epidermis) contains hairlike projections (cilia) in most echinoderms except ophiuroids; the body wall of crinoids has relatively few. The cilia produce a waving motion that carries food particles toward the mouth or removes unwanted particles from the body. The epidermis also contains glandular and sensory cells. The epidermis of skeletal elements such as spines and pedicellariae, which project from the body surface, often is worn away. The next layer, the dermis, includes the calcareous skeleton and connective tissues. Internal to the dermis are circular and longitudinal muscle layers. The extensive body cavity (coelom) is modified to form several specialized regions. Two subdivisions of the coelom are the perivisceral coelom and the water-vascular system. The perivisceral coelom is a large, fluid-filled cavity in which the major organs, particularly the digestive tube and sex organs, are suspended. Other regions of the coelom include the axial sinus (absent from adult holothurians and all echinoids), the madreporic vesicle, and the hyponeural sinus (often called the perihemal system).

Cilia

Alimentary and blood systems. The digestive canal consists of a tube, which is almost straight (asteroids and ophiuroids), coiled in a clockwise direction (crinoids and holothurians), or coiled first clockwise, then counterclockwise (echinoids). The tube may be divided into esophagus, stomach, intestine, and rectum. Specialized branches of the digestive tube enlarge the digestive surface and may serve other functions; *e.g.,* digestive glands of asteroids, diverticula of echinoids and crinoids, siphons in echinoids, and respiratory trees in holothurians. The anus, absent in ophiuroids and a few asteroids, is present in most groups. The mouth is near the centre of the oral surface, at the point of convergence of the areas containing the tube feet.

The blood system is a complex system of spaces that are neither part of the coelom nor true vessels. A hemal ring and five radial hemal canals surround the esophagus and radial canals of the water-vascular system. A sixth hemal space arises from the hemal ring and enters the axial organ. In addition, a complex network of hemal spaces is associated with the alimentary canal and gonads.

Hemal ring

Axial organ. The axial organ, a complex and elongated mass of tissue found in all echinoderms except holothurians, represents the common junction of the perivisceral coelom, the water-vascular system, and the hemal system. Although its functions are not yet well understood, the axial organ plays a part in defense against invading organisms, can contract, is responsible for a circulation of fluids, and may have excretory and secretory activity.

Nervous system and sense organs. The echinoderm nervous system is complex. In all groups, a nerve plexus lies within and below the skin. In addition, the esophagus is surrounded by one to several nerve rings, from which run radial nerves often in parallel with branches of the water-vascular system. Ring and radial nerves coordinate righting activity.

Although echinoderms have few well-defined sense organs, they are sensitive to touch and to changes in light intensity, temperature, orientation, and the surrounding water. The tube feet, spines, pedicellariae, and skin respond to touch, and light-sensitive organs have been found in echinoids, holothurians, and asteroids.

Reproductive system. The masses of sex cells that compose the gonads of crinoids fill special cavities in the arms or pinnules. Crinoids are the only echinoderms with gonads outside the main body cavity, probably because its volume is reduced. Asteroids typically have 10 gonads, two in each arm, which are located near the arm base, appearing as a feathery tuft or a mass of tubules resembling a bunch of grapes. The gonads of some species are arranged in rows along each arm. Concentricycloids have five pairs of saclike gonads (Figure 3). Ophiuroids have gonads attached to sacs that hang into the body cavity; the sacs, which open outside the body at the bases of the arms, may have one gonad or as many as 1,000.

Number of gonads

Regular echinoids typically have five gonads attached to the interambulacra. A duct from each gonad opens to the exterior near the anus. Most irregular echinoids have four gonads, some have three or five, a few have two; the ducts are on the upper surface of the body. Holothurians differ from all other living echinoderms in having a single gonad, which consists of branching or unbranched tubules; the tubules open into a single duct, which opens to the exterior near the front end of the body. Since many early fossil echinoderms have a single genital opening, or gonopore, it is assumed that these forms also had only one gonad; the condition in holothurians thus is regarded as primitive.

PALEONTOLOGY AND EVOLUTION

Extinct echinoderms. Because the phylum Echinodermata was already well diversified by the Lower Cambrian Period, a considerable amount of Precambrian evolution must have taken place. A Precambrian fossil from Australia has triradiate symmetry and a superficial resemblance to an edrioasteroid; it has been suggested that the triradiate condition may have been a precursor of pentamerous symmetry, and that this fossil is a "pre-echinoderm." Scientists speculate that the lack of Precambrian fossil echinoderms indicates that while the earliest echinoderms may have possessed a water-vascular system, they lacked a calcite skeleton and thus did not fossilize. While the fossil record of echinoderms is extensive, there are many gaps, and many questions remain concerning the early evolution of the group. Ancient echinoderms exhibited an extraordinary variety of bizarre body forms; the earliest classes seemed to be "experimenting" with body shapes and feeding mechanisms; most were relatively short-lived. Early echinoderms were adapted to life on the surface of hard or soft seafloors, though the burrowing habit may have been acquired relatively early by sea cucumbers.

Adaptation

Extant echinoderms. Relationships among the living classes of echinoderms have been the subject of debate for many decades. Some scientists believe that larval stages reflect the interrelationships of the groups; thus, because sea urchins and brittle stars have pluteus larvae, they form a natural group, and starfishes and sea cucumbers form another for the same reason. Some biochemical studies support this scheme. On the other hand, comparative anatomy and some paleontology studies suggest that brittle stars and starfishes may have originated from a crinoidlike ancestor and should be placed together, and their general star shape would support this. Modern sea cucumbers and sea urchins share a globoid body but little else; however, some fossil sea urchins with overlapping skeletal plates share several features with some sea cucumbers.

CLASSIFICATION

Distinguishing taxonomic features. The classification of the echinoderms underwent a great upheaval during the

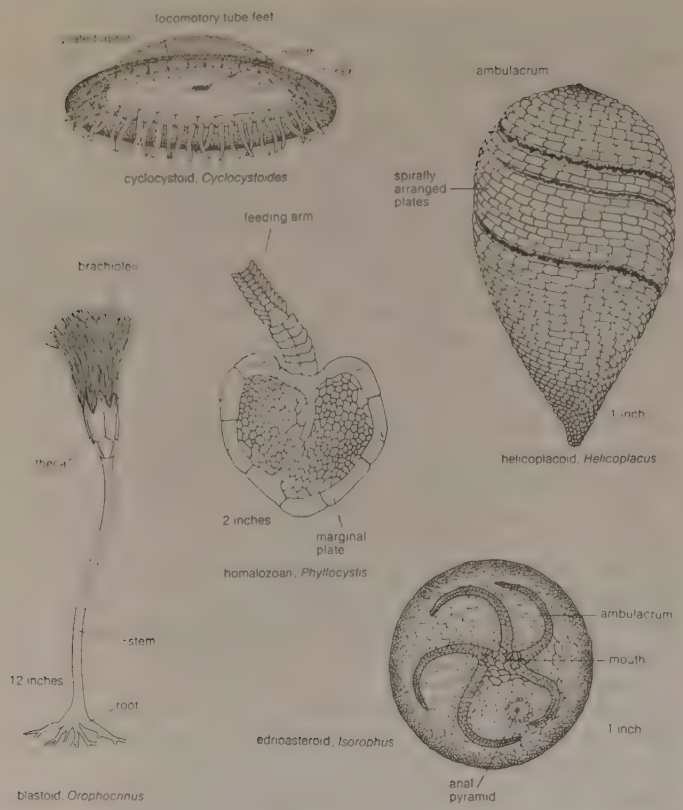

Figure 6: Representative extinct echinoderms. Approximate size is given for each.

From (cyclocystoid and blastoid) D. Nichols, *Echinoderms*, 4th ed. (1969), Hutchinson University Library, London, (homalozoan) G. Ubaghs, *Treatise on Invertebrate Paleontology*, part S (1957), University of Kansas and Geological Society of America, (helicoplacoid) J.W. Durham and K.E. Caster, "Helicoplacoidea: A New Class of Echinoderms," *Science*, vol. 140, pp. 820–822 (May 17, 1963), copyright 1963 by the American Association for the Advancement of Science, (edrioasteroid) R.V. Kesling and L. Mintz, *Contributions from the Museum of Paleontology*, University of Michigan, vol. 15, no. 14 (1960)

1970s and 1980s, and much disagreement remains. The five subphyla presented here are based upon combinations of characters: Homalozoa are asymmetrical; Blastozoa are stalked, with simple feeding apparatus; Crinozoa are stalked, with complex feeding apparatus; Asterozoa are star-shaped; Echinozoa are globoid to discoid. Below the subphylum level, the criteria for classification vary, but the skeleton is the most important; most groups can be characterized on the basis of skeletal characters alone.

Annotated classification. The echinoderms once were divided into two great groups, the Pelmatozoa and the Eleutherozoa, the names referring to living habits; pelmatozoans were attached to the seafloor for at least part of their life cycle while eleutherozoans were unattached animals capable of moving freely over the seafloor. It has been argued that such a separation is confusing, because each group contains a mixture of subgroups bearing no relationship to the evolutionary history of the phylum. The terms pelmatozoan and eleutherozoan are often used to describe the life habits of echinoderms. Some sea cucumbers, for example, have adopted a pelmatozoan habit, attaching themselves to rocks and feeding on plankton; others are eleutherozoan, moving about the seafloor while feeding, or even actively swimming.

The classification presented here is based upon current research by paleontologists and zoologists. Totally extinct classes, marked with a dagger (†), are known only as fossils.

PHYLUM ECHINODERMATA (echinoderms)

Marine invertebrates worldwide in distribution; skeleton composed of calcium carbonate in the form of calcite; most fossils and all living representatives with 5-part body symmetry (pentamerous); part of body cavity (coelom) comprises a water-vascular system. Cambrian to Recent. About 6,000 extant species, about 13,000 extinct species described.

†Subphylum Homalozoa (carpoids)

Middle Cambrian to Middle Devonian about 365,000,000–570,000,000 years ago; without 5-part symmetry; with fundamentally asymmetrical flattened body.

†Class Stylophora

Middle Cambrian to Upper Ordovician about 460,000,000–540,000,000 years ago; with unique single feeding arm sometimes interpreted as a stem.

†Class Homostelea

Middle Cambrian about 540,000,000 years ago; no feeding arm, but with stem of essentially 2 series of plates.

†Class Homoiostelea

Upper Cambrian to Lower Devonian about 400,000,000–510,000,000 years ago; with a feeding arm and a complex stem composed in part of more than 2 series of plates.

†Class Ctenocystoidea

Middle Cambrian about 540,000,000 years ago; no feeding arm and no stem, but with unique feeding apparatus consisting of a grill-like array of movable plates around mouth.

†Subphylum Blastozoa (blastozoans)

Cambrian to Permian about 280,000,000–540,000,000 years ago. Stalked echinoderms with soft parts enclosed in a globular theca (chamber) equipped with simple, erect food-gathering appendages (brachioles).

†Class Eocrinoidea

Lower Cambrian to Silurian about 430,000,000–570,000,000 years ago; body usually consisting of stem, theca, and feeding brachioles.

†Class Blastoidea

Silurian to Permian about 280,000,000–430,000,000 years ago; stem, theca with 18–21 plates arranged in 4 rings; numerous feeding brachioles; distinctive infoldings of theca (hydrospires) well developed.

†Class Paracrinoidea

Middle Ordovician about 460,000,000 years ago; with stem, theca, and arms with barblike structures (pinnules); plates of theca with pore system of unique type.

†Class Parablastoidea

Lower to Middle Ordovician about 460,000,000–500,000,000 years ago; resemble Blastoidea but differ in structure of ambulacra and in numbers of thecal plates.

†Class Rhombifera

Lower Ordovician to Upper Devonian about 350,000,000–500,000,000 years ago; theca globular; respiratory structures rhomboid sets of folds or canals.

†Class Diploporita

Lower Ordovician to Lower Devonian about 400,000,000–500,000,000 years ago; theca globular; respiratory structures pairs of pores.

Subphylum Crinozoa

Both fossil and living forms (Lower Ordovician about 500,000,000 years ago to Recent); with 5-part symmetry; soft parts enclosed in theca, which gives rise to 5 or more complex feeding arms.

Class Crinoidea (sea lilies and feather stars)

Lower Ordovician about 500,000,000 years ago to Recent; with, or secondarily without, a stem; theca reduced to small, cup-carrying hollow, usually branching, feeding arms with numerous small pinnules; includes fossil subclasses Camerata, Inadunata, and Flexibilia; living subclass Articulata, which includes stalked sea lilies and unstalked feather stars; about 700 living species.

Subphylum Asterozoa

Fossil and living forms (Lower Ordovician about 500,000,000 years ago to Recent); radially symmetrical with more or less star-shaped body resulting from growth of arms in 1 plane along 5 divergent axes; central mouth; 5 arms; dorsal tube feet and mouth.

Class Stelleroidea

Features as subphylum above.

†Class Somasteroidea

Lower Ordovician to Upper Devonian about 350,000,000 years ago. Superficially like Asteroidea, without a groove for tube feet.

Class Asteroidea (starfishes or sea stars)

Fossil and living forms (Middle Ordovician about 460,000,000 years ago to Recent); about 1,800 living species; arms broad, hollow; pinnate structure or arrangement of arms disrupted by dominant longitudinal growth axes; tube feet numerous, carried in grooves on the oral surface of the body; tube feet pointed or equipped with terminal suckers; respiration often by interradial gills on aboral surface of body; includes living orders Platyasterida, Paxillosida, Valvatida, Spinulosida, Forcipulatida, Notomyotida, and Brisingida.

Class Ophiuroidea (brittle stars or serpent stars)

Fossil and living forms (Ordovician about 460,000,000 years ago to Recent); disk sharply distinct from long, slender, solid arms; no furrow for tube feet; no suctorial tube feet; no anus; no pedicellariae; respiration by interradial gills on oral surface of body; includes living orders Oegophiurida, Phrynophiurida, and Ophiurida; about 2,000 living species.

Class Concentricycloidea (sea daisies)

Body flattened, disk-shaped, without obvious arms; water-vascular system with tube feet on oral surface of body; water-vascular canals form double ring; includes order Peripodida; 2 living species.

Subphylum Echinozoa

Fossil and living forms (Lower Cambrian about 570,000,000 years ago to Recent); radially symmetrical with fundamentally globoid body secondarily cylindrical or discoid; outspread arms or brachioles totally absent.

†*Class Cyclocystoidea*

Middle Ordovician to Middle Devonian about 375,000,000–460,000,000 years ago; small, disk-shaped; theca composed of numerous plates; ambulacral system with multiple branching.

†*Class Edrioasteroidea*

Lower Cambrian to Lower Carboniferous about 340,000,000–570,000,000 years ago; discoid to cylindrical; 5 well-developed straight or curved ambulacral food grooves radiate from a central mouth.

†*Class Edrioblastoidea*

Middle Ordovician about 375,000,000 years ago; stalked form with spheroidal theca; 5 well-developed food grooves.

†*Class Helicoplacoidea*

Lower Cambrian about 570,000,000 years ago; pear-shaped or spindle-shaped body with many plates arranged spirally.

†*Class Ophiocistioidea*

Lower Ordovician to Upper Silurian about 395,000,000–500,000,000 years ago; dome-shaped body partly or completely covered by well-developed test; 5 ambulacral tracts carry plated tube feet relatively enormous in size.

Class Holothuroidea (sea cucumbers)

Fossil and living forms (Ordovician about 460,000,000 years ago to Recent); cylindrical body, elongated orally–aborally, with mouth at or near one end, anus at or near the other; mouth surrounded by conspicuous ring of feeding tentacles; no spines or pedicellariae; single interradial gonad; skeleton usually reduced to form microscopic spicules; includes living orders Dendrochirotida, Dactylochirotida, Aspidochirotida, Elasipodida, Molpadiida, and Apodida; 1,100 living species.

Class Echinoidea (sea urchins, heart urchins, sand dollars)

Fossil and living forms (Ordovician 460,000,000 years ago to Recent); globular, discoid, or oval in shape, with complete skeleton (test) of interlocking plates bearing movable spines and pedicellariae; mouth directed downward; anus present; 5 or fewer interradial gonads. Includes subclass Perischoechinoidea with living order Cidaroida, and subclass Euechinoidea with living superorders Diadematacea and Echinacea (comprising the "regular" echinoids), and Gnathostomata and Atelostomata (comprising the "irregular" echinoids); 900 living species.

Critical appraisal. No classification satisfies everyone, and this is especially true for the echinoderms. Some modern scientists argue that fossils contribute little to our understanding of the interrelationships of living groups because fossil forms are different from recent forms and because many of the forms that link the groups in a classification scheme are missing. They believe instead that the higher classification of the echinoderms should be based upon a study of the embryology and anatomy of living groups and that the fossil groups should be inserted wherever they best seem to fit. In other classification schemes, scientists regard the fossils as a logical starting point—the "roots of the tree." A classification proposed in the early 1960s based upon growth patterns enjoyed wide acceptance until further research showed numerous flaws in the overall scheme. The current classification is decidedly a "hybrid," incorporating data from several fields of biologic research.

It has been strongly argued that some members of the subphylum Homalozoa are true chordates rather than echinoderms. This theory has not received wide acceptance. If it eventually proves to be correct, a drastic reevaluation of the Echinodermata would be required. The phylum would then share with chordates a latticelike calcite skeleton and a water-vascular system

New discoveries and new theories are continually reshaping the classification. The subphylum Blastozoa, proposed in the early 1970s, has gained wide acceptance. The extinct classes Helicoplacoidea and Ctenocystoidea were suggested in the 1960s, and their discovery caused a reassessment of the classification of the phylum. Extinct classes Lepidocystoidea and Camptostromatoidea have been eliminated and their members distributed among other echinoderm groups. The extant class Concentricycloidea was described in 1986 and is the first new class of living echinoderms to be named since 1821. Some argue that the concentricycloids are extreme forms of starfish that properly belong in the class Asteroidea. Less systematic importance is attached to the characters that are regarded as of class rank.

Eclipse, Occultation, and Transit

Eclipse, occultation, and transit are related astronomical events in which three celestial bodies are aligned; the body passing between the other two obscures some or all of the light of one of these as seen from the other. The difference in terminology is related to the relative sizes of the obscuring and obscured bodies.

The Sun is eclipsed when the Moon comes between it and the Earth; the Moon is eclipsed when it moves into the shadow of the Earth cast by the Sun. Eclipses of natural or artificial satellites of a planet occur as the satellites move into the planet's shadow. The two component stars of an eclipsing binary star move around each other in such a way that their orbital plane passes through or very near the Earth, and each star periodically eclipses the other as seen from the Earth.

When the apparent size of the eclipsed body is much smaller than that of the eclipsing body, the phenomenon is known as an occultation. Examples are the disappearance of a star, nebula, or planet behind the Moon, or the vanishing of a natural satellite or space probe behind some body of the solar system.

A transit occurs when, as viewed from the Earth, a relatively small body passes across the disk of a larger body, usually the Sun or a planet, eclipsing only a very small area: Mercury and Venus periodically transit the Sun, and a satellite may transit its planet.

This article is divided into the following sections:

PHENOMENA OBSERVED DURING ECLIPSES

Lunar eclipse phenomena. The Moon may, when full, enter the shadow of the Earth. The motion of the Moon around the Earth is from west to east relative to the Sun, so that, for an observer facing south, the shadowing of the Moon begins at its left edge (if the Moon were north of the observer, as, for example, in parts of the Southern Hemisphere, the opposite would be true). If the eclipse is a total one and circumstances are favourable, the Moon will pass through the umbra, or darkest part of the shadow, in about two hours (see Figure 1). During this time, the Moon is usually not quite dark. A part of the sunlight, especially the redder light, penetrates the Earth's atmosphere, is refracted into the shadow cone, and reaches the Moon. Meteorologic conditions on Earth strongly affect the amount and colour of light that can penetrate the atmosphere. Generally, the totally eclipsed Moon is clearly visible and has a reddish-brown, coppery colour, but the brightness varies strongly from one eclipse to another.

Total lunar eclipse

After the Moon leaves the umbra, it must still pass through the penumbra of the shadow. When the border between umbra and penumbra is visible on the Moon, the border is seen to be part of a circle, the projection of the circumference of the Earth. This is a direct proof of the spherical shape of the Earth. Because of the Earth's atmosphere, the edge of the umbra is rather diffuse, and the times of contact between the Moon and the umbra cannot be observed accurately.

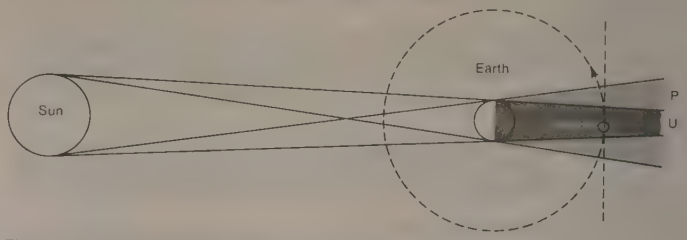

Figure 1: *Eclipse of the Moon.*
The Moon revolving in its orbit around the Earth passes through the shadow of the Earth. U (umbra) is the total shadow, P (penumbra) the partial shadow.

During the eclipse, the surface of the Moon cools at a rate dependent on the constitution of the lunar soil, which is not everywhere the same. Many spots on the Moon sometimes remain brighter than their surroundings during totality—particularly in their output of infrared radiation—possibly because their heat conductivity is less, but the cause is not fully understood.

Cooling of the lunar surface during eclipses

An eclipse of the Moon can be seen under similar conditions at all places on the Earth where the Moon is above the horizon.

Solar eclipse phenomena. Totality at any particular solar eclipse can only be seen from a relatively narrow belt on Earth. The various phases observable at a total solar eclipse are illustrated in Figure 2A. "First contact" designates the moment when the disk of the Moon, invisible against the bright sky background, just touches the disk of the Sun. The partial phase of the eclipse then begins, as a small indentation in the western rim of the Sun becomes noticeable. The dark disk of the Moon now gradually moves across the Sun's disk, and the bright area of the Sun is reduced to a crescent. The sunlight, shining through gaps in foliage and other small openings, is then seen to form little crescents of light that are images of the light source, the Sun. Toward the beginning of totality, the direct light from the Sun diminishes very quickly and the colour changes. The sky becomes dark, but, along

Figure 2: *Successive phases of a solar eclipse.*
The dark disk of the Moon gradually moves across the disk of the Sun from west (right) to east (left). (A) Total eclipse: (1) first contact; (2) partial phase; (3) second contact, beginning of totality; (4) third contact, end of totality; (5) partial phase; (6) fourth contact. (B) Partial eclipse: (1) first contact; (3) maximum phase; (5) last contact.

the horizon, the Earth's atmosphere still appears bright because the umbra of the Moon's shadow on the Earth extends over a rather narrow region. The scattered light coming in from a distance beyond this region produces weird effects. Men, birds, and other animals react with fear; birds may go to roost as they do at sunset.

Baily's beads

As the tiny, narrow crescent of sunlight disappears, little bright specks remain where depressions in the Moon's edge, the limb, are last to obscure the Sun's limb. These specks are known as Baily's beads, after the 18th-century English astronomer Francis Baily, who first drew attention to them. The beads vanish at the moment of second contact, when totality sets in. This is the climax of the eclipse. The reddish prominences and chromosphere of the Sun, around the Moon's limb, can now be seen. The brighter planets and stars become visible in the sky. The white corona extends out from the Sun to a distance greater than the Sun's diameter, at which point it fades completely. The temperature in the path of totality falls by some degrees. The light of totality is much brighter than that of the Full Moon but is quite different (see below).

The moment of third contact approaches, at which time many of the phenomena of second contact appear again in reverse order. Suddenly the first Baily's bead appears, now on the other side of the Moon. More beads of light follow, the Sun's crescent grows again, the corona disappears, daylight brightens, and the stars and planets fade from view. The thin crescent of the Sun gradually widens, and about one and a quarter hours later the eclipse ends with fourth contact, when the last encroachment made by the Moon on the Sun's rim disappears.

During the partial phase, both before and after totality, it is absolutely essential to protect the eyes against injury by the intense brilliance of the Sun. It should never be viewed directly except through strong filters, a dark smoked glass, or a heavily fogged photographic plate or film.

Shadow bands

When totality is imminent and only a small crescent of the Sun remains, the so-called shadow bands can often be seen on plain light-coloured surfaces, such as open floors and walls. These are striations of light and shade, moving and undulating, several centimetres (or inches) wide. Their velocity and direction depend on air currents at various heights, as they are caused by refraction of sunlight by small inhomogeneities in the Earth's atmosphere. A similar phenomenon is the projection of water waves on the bottom of a sunlit swimming pool or bath.

THE GEOMETRY OF ECLIPSES, OCCULTATIONS, AND TRANSITS

Eclipses of the Sun. An eclipse of the Sun takes place when the Moon comes between the Earth and the Sun so that the Moon's shadow sweeps over the face of the Earth (see Figure 3). This shadow consists of two parts: the umbra, or total shadow, a cone into which no direct sunlight penetrates; and the penumbra, or half shadow, which is reached by light from only a part of the Sun's disk.

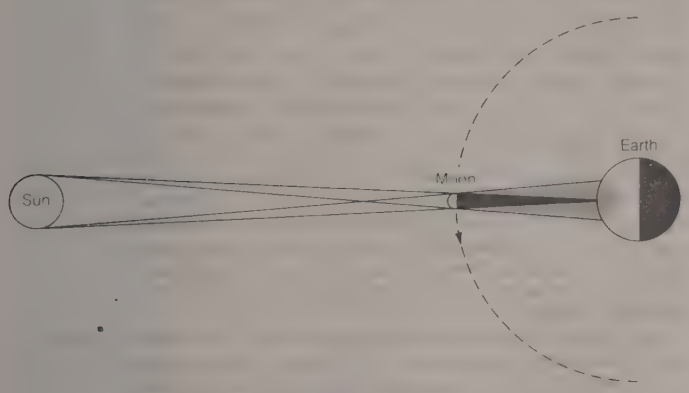

Figure 3: *Eclipse of the Sun.*
The shadow of the Moon sweeps over the surface of the Earth. In the darkly shaded region (umbra) the eclipse is total; in the lightly shaded region (penumbra) the eclipse is partial. The shaded region on the opposite side of the Earth indicates the darkness of night. (Dimensions of bodies and distances are not to scale.)

Total solar eclipse

To an observer within the umbra, the Sun's disk appears completely covered by the disk of the Moon; such an eclipse is called total. To an observer within the penumbra, the Moon's disk appears projected against the Sun's disk so as to overlap it partly; the eclipse is then called partial for that observer. The umbra cone is narrow at the distance of the Earth, and a total eclipse is observable only within the narrow strip of land or sea over which the umbra passes. A partial eclipse may be seen from places within the large area covered by the penumbra. Sometimes the Earth intercepts the penumbra of the Moon but is missed by its umbra; only a partial eclipse of the Sun is then observed anywhere on the Earth.

By a remarkable coincidence, the sizes and distances of the Sun and Moon are such that they appear as very nearly the same angular size (about 0.5°) at the Earth, but their apparent sizes depend on their distances from the Earth. The Earth revolves around the Sun in an elliptical orbit, so that the distance of the Sun changes slightly during a year, with a correspondingly small change in the apparent size, the angular diameter, of the solar disk. In a similar way, the apparent size of the Moon's disk changes somewhat during the month because the Moon's orbit is also elliptical. When the Sun is nearest to the Earth and the Moon is at its greatest distance, the apparent disk of the Moon is smaller than that of the Sun. If an eclipse of the Sun occurs at this time, the Moon's disk passing over the Sun's disk cannot cover it completely but will leave the rim of the Sun visible all around it. Such an eclipse is said to be annular. Total eclipses and annular eclipses are called central.

In a partial eclipse (Figure 2B), the centre of the Moon's disk does not pass across the centre of the Sun. After the first contact, the visible crescent of the Sun decreases in width until the centres of the two disks reach their closest approach. This is the moment of maximum phase, and the extent is measured by the ratio between the smallest width of the crescent and the diameter of the Sun. After maximum phase, the crescent of the Sun widens again until the Moon passes out of the Sun's disk at the last contact.

Eclipses of the Moon. When the Moon moves through the shadow of the Earth (see Figure 1) it loses its bright direct illumination by the Sun, although its disk still remains faintly visible. As the shadow of the Earth is directed away from the Sun, a lunar eclipse can occur only at the time of Full Moon—that is, when the Moon is on the side of the Earth opposite to that of the Sun. A lunar eclipse appears much the same at all points of the Earth from which it can be seen. When the Moon enters the penumbra, a penumbral eclipse occurs. The dimming of the Moon's illumination by the penumbra is so slight as to be scarcely noticeable, and penumbral eclipses are rarely watched. After a part of the Moon's surface is in the umbra and thus darkened, the Moon is said to be in partial eclipse. After about an hour, when the whole disk of the Moon is within the umbra, the eclipse becomes total. If the Moon's path leads through the centre of the umbra, the total eclipse can be expected to last about an hour and three-quarters.

Penumbral eclipse of the Moon

Eclipses, occultations, and transits of satellites. These phenomena are conveniently illustrated by the four largest satellites of Jupiter, whose eclipses provide a frequently occurring and fascinating spectacle to the telescopic observer. The three innermost moons (Io, Europa, and Ganymede) disappear into the shadow of Jupiter at each revolution, though the fourth (Callisto) is not eclipsed every time. Because of the sizable dimensions of these bodies, some minutes elapse between first contact with the shadow and totality. The orbits of these satellites lie nearly in the same plane as Jupiter's orbit around the Sun, and, at practically every revolution of each satellite, the following four eclipse phenomena take place: (1) eclipse of the satellite when it passes through Jupiter's shadow; (2) occultation of the satellite when it disappears behind the planet, as seen from the Earth; (3) transit of the satellite across the disk of Jupiter; and (4) transit of the shadow of the satellite across the planet's disk.

Figure 4 illustrates these phenomena; it shows Jupiter

and the orbit of one of its satellites, the direction of the sunlight illuminating the system, and the direction toward the Earth, from where the observation is made. When the satellite arrives at the point S_1 of its orbit, it enters Jupiter's shadow (eclipse) and vanishes. At S_2 it comes out of the shadow, but, to the terrestrial observer, it is now hidden behind the planet (occultation) until at S_3 it reappears at the limb. When the satellite reaches the position S_4, its shadow falls on Jupiter, causing a small dark spot on its surface. Seen from the Earth, the satellite is to the left of Jupiter approaching Jupiter's limb, at the time that its shadow spot passes across the planet's disk (transit of shadow). At S_5 the satellite starts to pass in front of the planet (transit of satellite), following its shadow spot. Both Jupiter and the satellite must have their illuminated sides facing the Earth. They differ little in total surface brightness; near the limb the satellite is somewhat brighter than the planet's surface on which it appears projected, but near the middle of the disk it is hardly distinguishable. At S_6 the shadow leaves the planet, and at S_7 the satellite emerges at the limb.

Proof of finite speed of light

Historically, the eclipses of Jupiter's satellites are important, for they provided one of the earliest proofs of the finite speed of light. It is possible to calculate with considerable precision the times of disappearance and reappearance of a satellite undergoing eclipse. The Danish astronomer Ole Rømer in 1675 noticed discrepancies between the observed and calculated times of such eclipses, which he correctly explained as being due to the difference in the travel time of light when the Earth is nearest to Jupiter or farther away from it.

A related phenomenon is the occultation of a space probe by a planet. During the beginning and the end of such an occultation, signals sent out by the spacecraft and received on Earth have penetrated the planet's atmosphere and can yield information about atmospheric density and composition.

On March 10, 1977, the planet Uranus passed between the Earth and a bright star. The event was observed by several teams of astronomers, who hoped to derive an accurate estimate of the diameter of the planet from their data. To their surprise, however, the light from the star was briefly obscured several times before and after the disk of Uranus occulted it. It was concluded that Uranus has a system of rings somewhat like those of Saturn.

THE FREQUENCY OF SOLAR AND LUNAR ECLIPSES

A solar eclipse, especially a total one, can be seen from only a limited part of the Earth, while the eclipsed Moon can be seen at the time of the eclipse wherever the Moon is above the horizon.

In most calendar years there are two lunar eclipses; in some years one or three or none occur. Solar eclipses occur two to five times a year, five being exceptional; there were five in 1935 and will be again in 2206. The average number of total solar eclipses in a century is 66 for the Earth as a whole.

Numbers of solar eclipses predicted to take place during the 20th to the 25th century are:

1901–2000:	228	eclipses,	of	which	145	are central
2001–2100:	224	"	"	"	144	" "
2101–2200:	235	"	"	"	151	" "
2201–2300:	248	"	"	"	156	" "
2301–2400:	248	"	"	"	160	" "
2401–2500:	237	"	"	"	153	" "

Any point on Earth may, on the average, experience no more than one total solar eclipse in three to four centuries. The situation is quite different for lunar eclipses. An observer remaining at the same place (and granted cloudless skies) can see 19 or 20 lunar eclipses in 18 years: three or four total eclipses and six or seven partial eclipses may be visible from beginning to end, and five total eclipses and four or five partial eclipses at least partially visible.

Duration of eclipses

All these numbers can be worked out from the geometry of the eclipses. A total lunar eclipse can last as long as an hour and three-quarters, but for a solar total eclipse maximum duration of totality is only 7½ minutes. This difference results from the fact that the Moon is much smaller in cross section than the extension of the Earth's shadow but can be only a little greater in apparent size than the Sun.

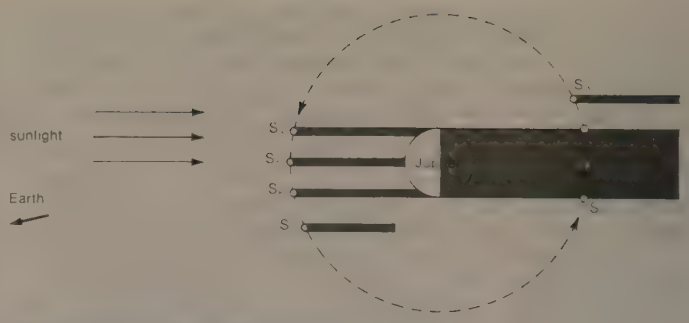

Figure 4: *Eclipses of the satellites of Jupiter.* S_1–S_7 mark successive positions of one of these satellites as it revolves in its orbit around Jupiter.

Cycles of eclipses. The eclipses of the Sun and Moon occur at New Moon and Full Moon, respectively, so that one basic time period involved in the occurrence of eclipses is the synodic month; *i.e.*, the time of one revolution of the Moon around the Earth with respect to the Sun.

Eclipses and the synodic month

A solar eclipse does not occur at every New Moon, because the Moon's orbit plane is inclined to the ecliptic, the plane of the orbit of the Earth around the Sun. The angle between the planes is about 5°; thus the Moon can pass well above or below the Sun. The line of intersection of the planes is called the line of the nodes, being the two points where the Moon's orbit intersects the ecliptic plane. The ascending node is the point where the Moon crosses the ecliptic from south to north, and the descending node that where it goes from north to south. The nodes move along the orbit from west to east, going completely around the ecliptic in about 19 years. The Moon's revolution from one node to the same node again (called the draconic month, 27.212220 days) takes somewhat less time than a revolution from Full Moon to Full Moon (the synodic month, 29.530589 days). For an eclipse to occur, the Moon has to be near one of the nodes of its orbit. The draconic month, therefore, is the other basic period of eclipses.

The saros period

Resonance between these two periods produces what is called the saros period, after which time Moon and Sun return very nearly to the same relative positions. The saros was known to the ancient Babylonians (see below *Use of eclipses for astronomical purposes: In ancient astronomy*). It comprises 223 lunations (the time period from New Moon to New Moon)—that is, 6,585.321124 days, or 241.9986 draconic months. This is nearly a whole number, so that the Full Moon is in almost the same position (*e.g.*, very near a node) at the beginning and end of a saros, a lapse of time equalling 18 years and 11⅓ days or 10⅓ days if five leap years fall within the period. Thus, there is usually a close resemblance between any eclipse and the one taking place 18 years and 11 days earlier or later. Since the date differs by only about 11 days in the calendar year, the latitudes on Earth of the two eclipses will be about the same, and so will the relative apparent sizes of Sun and Moon. The saros period also comprises 238.992 anomalistic months, again nearly a whole number. In one anomalistic month, the Moon describes its orbit from perigee to perigee, in which point it is nearest to the Earth. So the Moon's distance from the Earth is the same after a whole number of anomalistic months and very nearly the same after one saros. The saros period is, therefore, extremely useful for the prediction of both solar and lunar eclipses.

Because of the extra one-third day in the saros, the eclipse recurs each time approximately 120° farther west on the surface of the Earth. After three saroses, or 54 years and about a month, the longitude is repeated.

There is a regular shift on Earth to the north or to the south of successive eclipse tracks from one saros to the next. The eclipses occurring when the Moon is near its ascending node shift to the south, those happening when it is near its descending node shift to the north. A saros

series of eclipses begins its life at one pole of the Earth and ends it at the other. Every saros series lasts about 1,300 years and comprises 73 eclipses. About 42 of these series overlap at any time.

The inex period

Two consecutive saros series are separated by the inex period, 29 years minus 20 days—that is, 358 synodic months—after which time the New Moon has come from one node to the opposite node. The lifetime of an inex group is about 23,000 years, 70 groups coexisting, each comprising 780 eclipses. All other cycles in eclipses are combinations of the saros and the inex.

Prediction and calculation of solar and lunar eclipses. The problem may be divided into two parts. The first is to find out when an eclipse will occur, the other to determine when and where it will be visible.

For this purpose it is convenient first to consider the Earth as fixed and to suppose the observer looking out from its centre. To this observer, O in Figure 5, the Sun and Moon appear projected on the celestial sphere. While this sphere appears to him to rotate daily, as measured by the positions of the stars, around the line PP′ (the Earth's axis of rotation), the Sun's disk, S, appears to travel slowly along the great circle EE′ (the ecliptic), making a complete revolution in one year. At the same time the Moon's disk, M, revolves along the circle LL′ once during a lunar month. The angular diameters of the two disks S and M are each about 0.5° but vary slightly.

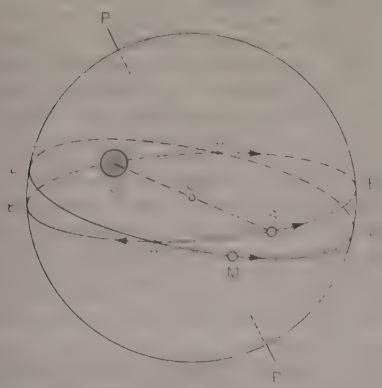

Figure 5: Apparent motions of the Sun and the Moon on the celestial sphere (see text).

Every month the Moon's disk revolving along LL′ will overtake the more slowly moving Sun once, at the moment of New Moon. Usually the Moon's disk will pass above or below the Sun's disk. Overlapping of the two results in an eclipse of the Sun, which can happen only when the New Moon occurs at a moment when the Sun is near the points ☊ or ☋; these signs denote the ascending and descending nodes of the Moon's orbit.

The crosscut of the umbra, the shadow cone of the Earth, at the distance of the Moon (as shown in Figure 5), may be projected like a disk U onto the celestial sphere. It subtends an angle of about 1.4°; its centre will always be opposite to the Sun's disk and travel along EE′. A lunar eclipse occurs whenever the Moon's disk overlaps the shadow disk; this happens only when the shadow disk is near one of the nodes or the Sun is near the opposite node. The Sun's passage through the lunar nodes is thus the critical time for both solar and lunar eclipses. The Moon's orbit plane, represented by the circle LL′, is not fixed, and its nodes move slowly along the ecliptic in the direction indicated by the arrow, making a complete revolution in about 19 years. The interval between two successive passages of the Sun through one of the nodes is termed an "eclipse year," and, since the Moon's node moves so as to meet the advancing Sun, this interval is about 18.6 days less than a tropical (or ordinary) year.

The eclipse year

In Figure 6 the region of the ascending node as seen from the centre of the sphere is much enlarged. Here the node is kept fixed and the apparent motions of the Sun and the Moon are shown relative to the node. To the imaginary observer at the centre of the Earth, the Sun's disk will travel along the circle EE′, the Moon's disk along

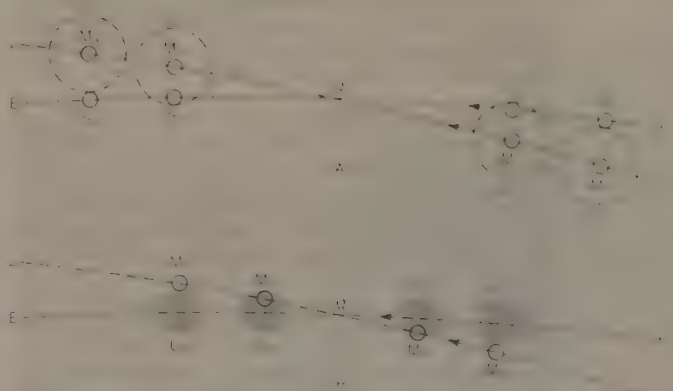

Figure 6: *Ascending node of the Moon's orbit as seen from the centre of the sphere.*
Conditions necessary for (A) a solar eclipse and (B) a lunar eclipse (see text).

LL′. The Sun is so distant compared with the size of the Earth that, from all places on the Earth's surface, the Sun is seen nearly in the same position as from the centre. But the Moon is relatively near and its projected position on the celestial sphere is different for various observing stations on the Earth; it may be displaced as much as 1° from the position in which it is seen from the centre of the Earth. If the radius of the Moon's disk is enlarged by 1°, a circle, C, is obtained that encloses all possible positions of the Moon's disk seen from anywhere on the Earth. Conversely, if any circle of the Moon's size is drawn inside this "Moon circle," C, there is a place on the Earth from which the Moon is seen in that position.

Accordingly, an eclipse of the Sun occurs somewhere on Earth whenever the Moon overtakes the Sun in such a position that the Moon circle, C, passes over the Sun's disk; when the latter is entirely covered by the Moon circle, the eclipse will be central (*i.e.*, total or annular). From Figure 6A, it is evident that a solar eclipse will take place if a New Moon occurs while the Sun moves from S_1 to S_4. This period is the eclipse season; it starts 19 days before the Sun passes a node and ends 19 days thereafter. Since there is a New Moon every month, at least one solar eclipse, and occasionally two, occurs during every eclipse season—of which there are two in each calendar year. A fifth solar eclipse during a calendar year is possible because part of a third eclipse season may occur at the beginning of January or at the end of December.

The eclipse season

Figure 6B illustrates the condition necessary for a lunar eclipse. If a Full Moon occurs within 13 days of a node passage of the Sun (when the shadow disk, U, passes the ascending node), the Moon will be eclipsed. Most eclipse seasons, but not all, will thus also contain a lunar eclipse. When three eclipse seasons fall in a calendar year, there may be three lunar eclipses in that year. Eclipses of the Sun are evidently more frequent than those of the Moon. Solar eclipses, however, can only be seen from a very limited region of the Earth, whereas lunar eclipses are visible from an entire hemisphere.

During a solar eclipse the shadow cones (umbra and penumbra) of the Moon sweep across the face of the Earth (Figure 3), while at the same time the Earth is rotating on its axis. Within the narrow area covered by the umbra, the eclipse is total. Within the wider surrounding region covered by the penumbra, the eclipse is partial.

The astronomical ephemerides, or tables, published for each year provide maps tracing the paths of the more important eclipses in considerable detail, as well as data for accurate calculation of the times of contact at any given observing station. Calculations are made some years ahead in Ephemeris Time (ET), which is defined by the orbital motion of the Earth and the other planets. At the time of the eclipse, the correction is made to Universal Time (UT), which is defined by the rotation of the Earth and is not rigorously uniform.

Accurate short-range predictions

It is possible with the aid of modern tables to accurately predict solar eclipses several years ahead. For predictions

of longer range, the main uncertainty is that of the Moon's motion. Eclipses can of course be "predicted backward" as well as forward, and the calculation of ancient eclipses has been of value in historical research.

ECLIPSE RESEARCH ACTIVITIES

Solar research. During a solar eclipse, the Moon serves as a screen outside the Earth's atmosphere. As seen from the Earth, the Moon's dark projection on the Sun crosses the Sun at approximately 350 kilometres (220 miles) per second. For a few seconds, the bright, ordinarily visible disk of the Sun, called the photosphere, is eclipsed, while the chromosphere, the lower solar atmosphere, remains visible at the Sun's edge. During this brief time, light emitted from the chromosphere can be studied and its decrease in intensity with height above the photosphere can be measured. Discrimination between layers within the chromosphere is possible to some extent. An instrument called the coronagraph has been developed to obscure the brilliant photosphere artificially at times outside of eclipses, but the study of the thin layers of the solar chromosphere and corona is still best done during an eclipse.

The first photograph of a solar eclipse was taken in 1851, and the first of scientific importance by the British scientist and inventor Warren de la Rue and the Italian astronomer Angelo Secchi in 1860.

Spectroscopic observations. The ordinary spectrum of the Sun contains a brilliant multicoloured background—the continuum. This radiation emanates primarily from the lower layers of the solar atmosphere. Cooler atoms higher up, however, selectively absorb the radiations, so that the solar spectrum consists of the bright rainbow background with many narrow gaps—dark lines—where the light has been absorbed.

Spectroscopy was first applied to the eclipsed Sun in 1868, when the path of totality passed over India and Malaya and the spectrum of bright lines originating in the solar prominences was observed. The British astronomer Joseph Norman Lockyer thought that one of these spectral lines was emitted by an unknown chemical element, which he called helium (from Greek *hēlios,* "sun"); helium was not identified on Earth until 1895.

At the moment of totality, when the Moon obliterates the last trace of the bright photosphere, with its dark-line spectrum, the light from the upper tenuous layers of the solar atmosphere (which is usually lost in the much brighter photospheric light) flashes into view with the characteristic bright-line spectrum of a luminous gas. This spectrum, first observed in 1870, disappears within four to five seconds, as the Moon moves across the disk of the Sun. Because of its evanescent character, it is called the flash spectrum. A second flash occurs at the end of totality. Analysis of flash spectra has led to some surprising results. The spectrum matches the dark-line spectrum only roughly. The lines of the neutral metals are of comparable strength in the two spectra, but those of the ionized metals (*i.e.,* those made up of atoms that have lost one or more electrons) are markedly enhanced in the flash spectrum. The difference is attributed, in part, to lower pressures in the upper layers of the solar atmosphere, but high temperature appears to contribute to the increased excitation. This condition is especially true for the flash lines of ionized helium, which do not appear at all in the ordinary dark-line spectrum. Such flash lines require excitation temperatures of at least 25,000 K (about 45,000° F) for their production, whereas the temperature required to produce the observed quality and quantity of bright emission from the surface is only 6,000 K.

Flash-spectrum analysis

Other observations. Extending upward from the chromosphere, and closely related to it, are the so-called prominences, one of the striking features of a total eclipse, which project outward into space. They appear as rose-coloured patches of flame, projecting well beyond the limb of the Moon, and consist of long interlacing filaments of incandescent gas.

The corona of the Sun can be seen during totality. One of the most beautiful of natural phenomena, the solar corona shines like finely etched white frost against the deep blue of the eclipse-darkened sky. The form of the corona presented at different eclipses is almost infinitely variable. On occasion, usually when sunspots are near a minimum, long streamers extend four or five solar diameters away from the Sun. At other times, especially close to sunspot maximum, the corona is more nearly circular but with jagged, petallike extensions. The corona is faint, about 500,000 times less brilliant than the Sun itself. Consequently, the sky glare surrounding the Sun ordinarily hides the coronal details, and, before the development of the coronagraph, it was believed to be impossible to record the corona except during an eclipse.

Solar corona

Also interesting are observations of the radio emission of the Sun during a solar eclipse. When the Moon crosses different parts of the Sun, inhomogeneities in the generation of solar radio waves can be localized.

For geodetic purposes (measuring the Earth), the exact timing of the moments of the contacts of Moon and Sun are important, because these depend on the site of observation and so on the shape of the Earth.

The Sun's ultraviolet and X radiation help create and influence the ionosphere, a region in the Earth's upper atmosphere where many atoms are ionized. The ionosphere changes during an eclipse as the ionizing radiation is cut off. So that observations of the ionosphere made during an eclipse can be interpreted correctly, it is necessary to predict the times and phases of the eclipse as it reaches the high layers of the atmosphere, where they may be quite different from times and phases on the surface.

Tests of relativity during solar eclipse. One of the predictions of the general theory of relativity, as presented by Einstein in 1915, is the deflection of light rays by a gravitational field—that of the Sun, for example. According to this theory the deflection, which causes the image of a star to appear slightly too far from the Sun's image, amounts to 1.75 seconds of arc at the limb of the Sun and decreases in proportion to the apparent distance from the centre of the solar disk of the star whose light is deflected. This is twice the amount given by the older Newtonian dynamics if light is assumed to have inertial properties. If light does not have such properties, as is generally accepted now, the Newtonian deflection is zero. To test the theory, it is necessary to have extremely precise measurements of as many stars as possible around the Sun, and preferably close to it. The brightness of the corona prevents observation of stars closer to the Sun than one solar diameter. During totality the sky around the Sun is photographed with long-focus cameras to give the largest possible scale. The equipment is left in place, and about half a year later the same region of the sky with the same stars can be photographed again, this time during the night and without the Sun's disturbing gravity field. Comparison of the two sets of photographs shows the amount of gravitational displacement of starlight by the Sun and serves as a test of theory. Results of a number of eclipse observations made since 1918 have verified Einstein's prediction, though the deduced values are somewhat uncertain as a consequence of the small displacement.

Verification of Einstein's prediction

Lunar research. Lunar eclipses can yield information about the cooling of the Moon's soil when the Sun's radiation is suddenly removed and, therefore, about the soil's conductivity of heat and its structure. Infrared and radio-wavelength radiations from the Moon decline in intensity more slowly than does visible light emission during an eclipse because they are emitted from below the surface, and measurements indicate how far the different kinds of radiation penetrate into the lunar soil. Infrared observations show that at many "bright spots" the soil retains its heat much longer than in surrounding areas. Because of the absence of a lunar atmosphere, the solid surface is exposed to the full intensity of ultraviolet and particulate radiation from the Sun, which may give rise to fluorescence in some rock materials. Observations during lunar eclipses have given positive results for this phenomenon, with the appearance of abnormal bright regions in the obscured parts of the Moon.

TRANSITS OF MERCURY AND VENUS

At the time of inferior conjunction (*i.e.,* when moving between the Earth and the Sun) Mercury, seen from the

Earth, usually passes north or south of the Sun because of the inclination of its orbit. But if the conjunction occurs when Mercury is near one of the nodes of its orbit, the planet crosses the disk of the Sun as a small black circular spot, visible only with a telescope. Since the Earth passes Mercury's nodes on May 7 and November 9, transits can occur only near those dates. The shortest interval between two successive transits is seven years.

Transits of Venus can be seen without a telescope if the eyes are properly protected. When the transit is central, it takes about eight hours. The phenomenon is rare and can happen only within a day or two of the dates when the Earth passes the nodes of Venus' orbit—that is, on June 7 and December 8. The transits occur in pairs, with an interval of eight years between members of a pair; between the pairs, more than 100 years elapse.

Transits of Venus are helpful in finding the parallax and from it the distance of the Sun, as first pointed out by the British astronomer Edmond Halley in 1679. Parallax is the apparent difference in direction of an object when observed from different positions. The transits of June 1761 and 1769 and those of December in 1874 and 1882 were, thus, extensively observed. The next pair of transits of Venus are expected on June 8, 2004, and June 6, 2012.

One kind of observation for determining parallax consists in fixing the times of the contacts of the disks of the planet and the Sun from different points on the Earth. The observers at past transits became aware of a few remarkable phenomena. When Venus was partially overlapping the disk of the Sun, the part of the limb of the planet that extended beyond the Sun was seen to be surrounded with a radiant aureole, which observers of the transit in 1761 ascribed to the presence of an atmosphere on Venus. A second phenomenon was seen just after second and before third contact (see Figure 1), when Venus just touched the Sun's limb on the inside; this consisted in the development of a little dark connection—the so-called black drop—between Venus and the limb. Because of the black drop, the times of contact could not be sharply defined. Presumed causes of the black drop are diffraction, atmospheric agitation, and instrumental factors.

The black drop

The amount of sunlight intercepted during a transit depends on the diameter of the planet, and measuring this amount of sunlight may be one of the most accurate ways of determining the planet's diameter.

OCCULTATIONS BY THE SUN AND MOON

The occultation of the Crab Nebula by the solar corona, the extensive outer atmosphere of the Sun, takes place each year in June. The Crab Nebula is a radio source (Taurus A), and, when the occultation occurs, its pattern of radio emission is observed to broaden significantly. The broadening is attributed to scattering of radio-frequency radiation by the density irregularities in the extended corona. The nearest approach of Sun and Crab Nebula is at about five solar radii; the scattering is brought into evidence up to 60 solar radii.

The Moon sometimes occults a planet (see Figure 7) but very often occults a star. As a consequence of the inclination of the Moon's orbit with respect to the ecliptic (the Sun's apparent annual path) and the movement of the nodes of the Moon's orbit, all the stars in a belt of 10° around the ecliptic are occulted at some time during a period of about nine years. Among these are the bright stars Aldebaran, Regulus, Spica, and Antares, the star clusters Pleiades, Hyades, and Praesepe, and the Crab Nebula.

Lunar occultation of stellar bodies

Since the Moon always moves eastward, an occulted star disappears at the Moon's eastern limb and reappears at the western. These phenomena can be best observed at the dark limb of the Moon.

Efforts have been made to determine the apparent diameter of stars by accurately estimating the time they take to disappear behind the Moon; with modern optics and electronic devices this would not be impossible in some cases. But there are complications of two kinds: first, many stars are close binaries (doubles); and, second, the decline of the light of the occulted star shows an optical phenomenon called a diffraction pattern. However, for the purpose of yielding basic data on the perturbations (disturbances) in the Moon's orbit and on irregularities in the rotation of the Earth, the exact times of star occultations are still of value.

Griffith Observatory, Paul Roques

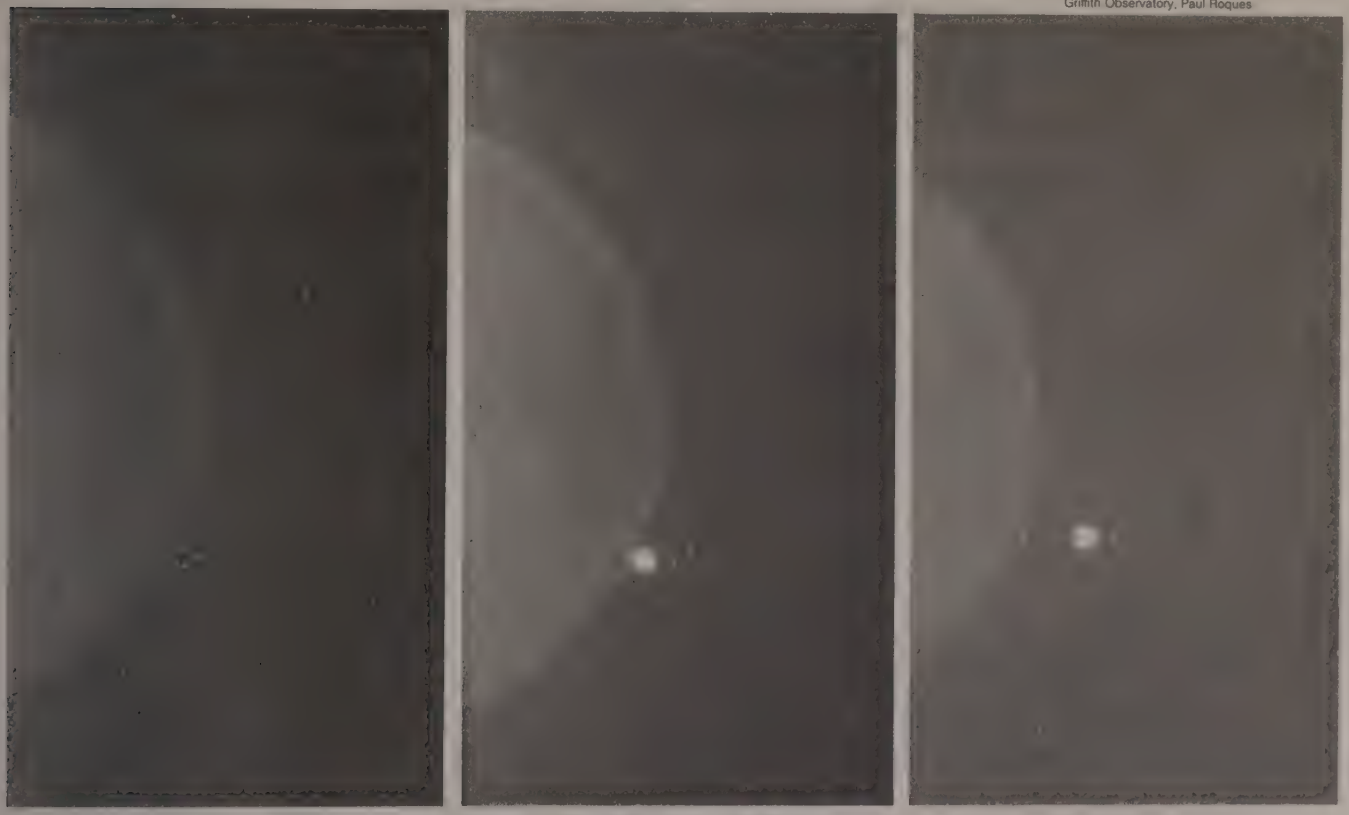

Figure 7: (Left to right) The emergence of Jupiter and three of its satellites after their occultation by the Moon.

The disappearance or reappearance of Jupiter takes more than one minute, but the time for a minor planet is under one second, and that for even a giant star like Aldebaran or Antares is less still, by a factor of 10. Other stars disappear nearly instantaneously, indicating that the Moon has no sensible permanent atmosphere.

ECLIPSING BINARY STARS

When, in a binary system (a double star whose components orbit a common centre), one component comes between the other and the Earth, an eclipse occurs and the amount of light received from both stars together is reduced; a total eclipse gives the greatest reduction, and the light is reduced to a minimum. Two eclipses occur during each revolution. The first star shown to have light that varied through eclipses in this way was Algol (Beta Persei). Its variability was discovered in 1667 by the Italian astronomer Geminiano Montanari, but its periodicity was not discovered and the explanation of the phenomenon as an eclipsing variable was not proposed until a century later by the English astronomer John Goodricke. At present, about 3,000 eclipsing binaries are known.

The many possible sizes of the two stars, in relation both to each other and to the size and tilt of their orbits, combined with the eccentricity (deviation from the circular) of the orbits, lead to a large variety of ways in which the light of the system changes during a revolution: the so-called light curve.

If the orbits of the two stars are not circular, then the motion in the orbits is not uniform but is most rapid near periastron (stars closest together) and least rapid near apastron (stars farthest apart). Therefore, the eclipses may not be equally spaced in time, as they are in the case of circular orbits. Study of the spacing and durations of the light minima will yield both the eccentricity and the orientation of the orbits. A steady change in the spacing of the minima as well as in their relative duration means that the line of apsides (major axis of the relative orbit) is rotating; the most rapid such rotation known is that of the eclipsing binary GL Carinae.

If the two stars are unequal in size, they may wholly overlap for some time. When the star of higher surface brightness is behind, the resulting eclipse is darker than that resulting when the brighter star cuts off the light of the dimmer one. Limb darkening, the tendency for a star to appear less brilliant near the edge of its apparent disk, also influences the shape of the light curves, and the amount of limb darkening present may be determined from those curves.

Limb darkening

Spectroscopic studies of the light of a double star allow determination of the ratio of the masses of the components to each other. The sum of the masses, however, can only be determined if the inclination of the orbit is known. In the case of an eclipsing binary, the plane of the orbit is known to be directed to the Earth. Therefore, eclipsing binaries can be made to reveal complete information about their masses.

A rapidly rotating star bulges at its equator. Also, many double stars are so close together that they distort each other tidally; in the case of very close pairs, this distortion has caused them to turn always the same sides toward each other. If such stars are eclipsing binaries, the amount of distortion can, in some cases, be determined from the light curve. For some stars the ratio of the long axis of the star to the short has been found to be as great as 5:3.

There are a few star systems like Algol, notably Zeta Aurigae, in which the difference in the sizes of the components is so great that the crossing of the smaller, brighter star before the disk of the supergiant companion should really be called a transit rather than an eclipse. This particular star has the remarkably long orbital period of 972 days and consists of an orange supergiant having a diameter of almost 300,000,000 kilometres and a substantially smaller, brighter star, only about three times larger than the Sun. The secondary minimum lasts for 38 days, and a very sensitive photometer must be used to detect the extremely slight fading of light when the smaller star is shining through the extended, tenuous atmosphere of the large one.

The star Zeta Aurigae

ECLIPSES IN HISTORY

In ancient and medieval times, eclipses of both the Sun and the Moon were often regarded as portents; hence, it is not surprising that many of these events are mentioned in history and in literature, as well as in astronomical writings.

Well over 1,000 individual eclipse records are extant from various parts of the ancient and medieval world. Most known ancient observations of these phenomena originate from three countries: Babylonia, China, and Greece. No records appear to have survived from ancient Egypt or India. Whereas virtually all Babylonian accounts of eclipses are confined to astronomical treatises, those from China and Greece are found in historical and literary works as well. Eclipses are noted from time to time in surviving European writings from the early Middle Ages. At this time only the Chinese, however, continued to observe and record such events on a regular basis, and this tradition continued almost uninterrupted down to recent centuries. Many eclipses were carefully observed by the astronomers of Baghdad and Cairo between about AD 800 and 1000. About AD 800 both European and Arab annalists began to include in their chronicles accounts of eclipses and other remarkable celestial phenomena. Some of these chronicles continued until the 14th or 15th century. Toward the end of this period, European astronomers commenced making fairly accurate measurements of the time of day or night when eclipses occurred, and this pursuit spread rapidly following the invention of the telescope.

The value of ancient and medieval records may be classified as follows, although it should be emphasized that there is some overlap between these individual categories: (1) literary and historical, depending on the interest that these records aroused and their connection with historical events; (2) chronological, insofar as they make it possible to verify chronological systems resting on other evidence and to supply dates for events concerned with eclipses; and (3) astronomical, including the determination by ancient astronomers of the periods and motions of the Sun and the Moon and by modern astronomers of variations in the length of the mean solar day.

The Sun is normally so brilliant that the casual observer is liable to overlook those eclipses in which less than about 80 percent of the solar disk is obscured. Only when a substantial proportion of the Sun is covered does the loss of daylight become noticeable. Hence it is rare to find references to small partial eclipses in literary and historical works. At various times, astronomers in Babylonia, China, and the Arab lands systematically reported eclipses of small magnitude but their vigilance was assisted by their ability to make approximate predictions. They thus knew roughly when to scrutinize the Sun. Arab astronomers sometimes viewed the Sun by reflection in water to diminish its brightness when watching for eclipses. The Roman philosopher and writer Seneca (*c.* 4 BC–AD 65), on the other hand, recounts that in his time pitch was employed for this purpose. It is not known, however, whether such artificial aids were used regularly.

When the Moon covers a large proportion of the Sun, the sky becomes appreciably darker and stars may appear. On those rare occasions when the whole of the Sun is obscured, the sudden occurrence of intense darkness, accompanied by a noticeable fall in temperature, may leave a profound impression on eyewitnesses. Total or near-total eclipses of the Sun are of special chronological importance. On average, they occur so infrequently at any particular location that if the date of such an event can be established by historical means to within about a decade, it may well prove possible to fix an exact date by astronomical calculation.

Importance of total or near-total solar eclipses

The Full Moon is much dimmer than the Sun, and lunar eclipses of even quite small magnitude are thus fairly readily visible to the unaided eye. Both partial and total obscurations are recorded in history with comparable frequency. As total eclipses of the Moon occur rather often (every three or four years on average at a given place), they are of less chronological importance than their solar counterparts. There are, however, several notable exceptions to this rule, as will be discussed below.

Literary and historical references. *Old Babylonian.* The earliest known references to eclipses for which dates can be established with reasonable confidence go back to the 21st century BC. These are recorded on the series of astrological tablets from Ur known as *Enūma Anu Enlil.* Several of these texts contain lunar eclipse *omina*—warnings of disasters that might follow an eclipse based on past coincidences between celestial and terrestrial occurrences. Some of the *omina* are so detailed that they are clearly based on observation of a specific eclipse. The example cited below is found on tablet 20 of the series:

> If in Simanu [lunar month III] an eclipse occurs on day 14, the [Moon-] god in his eclipse is obscured on the east side above and clears on the west side below, the north wind blows, [the eclipse] commences in the first watch of the night and it touches the middle watch. . . . by this the [Moon-] god gives a decision for Ur and the king of Ur. The king of Ur will see a famine, there will be many deaths, the king of Ur will be wronged by his son; the son who has wronged his father, the Sun-god will catch him, and he will die at the burial of his father. A son of the king who was not named for kingship will then occupy the throne.

From a careful investigation of the historical and astronomical circumstances, it has been shown that the eclipse referred to here is very likely to have been associated with the murder of Shulgi by his son and the accession of Amar-Sin. The most probable date for the eclipse is April 4, 2094 BC. A further lunar eclipse 42 years later regarded as signaling the destruction of Ur has been dated to April 13, 2053 BC.

Chinese. According to long-established tradition, the history of astronomy in ancient China could be traced back to before 2000 BC. The earliest surviving relicts that are of astronomical significance date from nearly a millennium later, however. The An-yang oracle bones (inscribed turtle shells, ox bones, and so forth) of the Shang dynasty (*c.* 1550–1050 BC), which have been uncovered near An-yang in northeastern China, record several eclipses of both the Sun and the Moon. The following report is an example:

Early Chinese references

> On day *kuei-yu* [the 10th day of a 60-day cycle], it was inquired [by divination]: "The Sun was eclipsed in the evening; is it good?" On day *kuei-yu* it was inquired: "The Sun was eclipsed in the evening; is it bad?"

The above text provides clear evidence that eclipses were regarded as omens at this early period (as is true of other celestial phenomena). Such a belief was extremely prevalent in China during later centuries. The term translated here as "eclipse" (*chih*) is the same as the word "eat." The Shang people thought that some monster was actually devouring the Sun or Moon during an eclipse. Not until many centuries later was the true explanation known; but by then the use of the term *chih* was firmly established to describe eclipses, and so it continued throughout Chinese history. As the year in which an eclipse occurred is never mentioned on the preserved oracle bones (many of which are mere fragments), dating of these observations by astronomical calculation has proved extremely difficult. A recent investigation of five lunar eclipses yielded likely dates between 1200 and 1180 BC. Shang chronology, however, is still very uncertain.

The *Shih ching* ("Classic of Poetry") contains a lamentation occasioned by an eclipse of the Moon followed by an eclipse of the Sun. The text, dating from the 8th century BC, may be translated:

> The Sun was eclipsed, a thing of very evil omen. Then the Moon became small, and now the Sun became small. . . . For the Moon to be eclipsed is but an ordinary matter. Now that the Sun has been eclipsed—how bad it is!

The solar eclipse is said to have occurred on the day *hsin-mao* (the 28th day of the sexagenary cycle), which was the first day of the 10th lunar month. A date of 776 BC was formerly adopted for such an event, but modern computations show that no solar eclipse in that year was visible in China. A revised date of 735 BC has been proposed. The different attitudes toward solar and lunar eclipses at this time is interesting. Throughout the subsequent thousand years or so, lunar eclipses were hardly ever reported in China—in marked contrast to solar obscurations, which were systematically observed.

After about 200 BC, a wide variety of celestial phenomena began to be noted in China on a regular basis. Summaries of these records are found in astronomical treatises contained in the official dynastic histories. In many instances, a report is accompanied by a detailed astrological prognostication. For example, the *Hou-Han shu* ("History of the Later Han Dynasty") contains the following account under a year corresponding to AD 119–120.

> On the day *wu-wu*, the 1st day of the 12th lunar month, the Sun was eclipsed; it was almost complete. On the Earth it became like evening. It was 11 degrees in the constellation of the Maid. The woman ruler [*i.e.*, the Empress Dowager] showed aversion to it. Two years and three months later, Teng, the Empress Dowager, died.

The date of this eclipse on the Chinese calendar is equivalent to January 18, AD 120. On this exact day there had occurred an eclipse of the Sun that was very large in China. Such chronological precision is typical of almost all Chinese records of celestial phenomena. The above-cited text is particularly interesting because it clearly describes an obscuration of the Sun, which, though causing dusk conditions, was not quite total where it was seen. The place of observation was probably Lo-yang, the Chinese capital of the time. With regard to the accompanying prognostication, it should be pointed out that a delay of two or three years between the occurrence of a celestial omen and its presumed fulfillment is quite typical of Chinese astrology.

Assyrian. The Assyrian eponym canon, which preserves the names of the annual magistrates who gave their names to the years (similar to the Athenian archons or Roman consuls), records under the year that corresponds to 763–762 BC: "Insurrection in the city of Ashur. In the month Sivan [equivalent to May–June], the Sun was eclipsed." The reference must be to the eclipse of June 15, 763 BC, the only large solar eclipse visible in Assyria over a period of many years. A possible allusion to the same eclipse is found in the Old Testament: " 'And on that day,' says the Lord God, 'I will make the sun go down at noon, and darken the earth in broad daylight' " (Amos 8:9). Amos was prophesying during the reign of King Jeroboam II (786–746 BC), and the eclipse would be very large throughout Israel.

Jewish. Apart from Amos, the only Old Testament writer to allude to eclipses is Joel (2:31). The most direct account of an eclipse in ancient Jewish history occurs not in the Bible but in the writings of Flavius Josephus, the 1st-century-AD historian. Not long before the death of Herod the Great, Josephus recounts the occurrence of a lunar obscuration:

References in early Jewish writings

> As for the other Matthias who had stirred up the sedition, he [Herod] had him burned alive along with some of his companions. And on that same night there was an eclipse of the Moon. But Herod's illness became more and more severe. . . .

This eclipse occurred shortly before the Passover festival. Calculation shows that the only springtime lunar eclipses visible in Israel between 17 BC and AD 3 took place on March 23, 5 BC and March 13, 4 BC. The former was total, while on the latter occasion about one-third of the Moon was covered. These two dates are conveniently close to one another, although the latter date is usually preferred by chronologists, implying that Herod died in the spring of 4 BC.

Greek. In a fragment of a lost poem by Archilochus occur the words:

> Nothing there is beyond hope, nothing that can be sworn impossible, nothing wonderful, since Zeus, father of the Olympians, made night from mid-day, hiding the light of the shining Sun, and sore fear came upon men.

This seems a clear reference to a total eclipse. The phenomenon has been identified as the eclipse on April 6, 648 BC, which was total in the Aegean and occurred during Archilochus' lifetime.

Small fragments survive of other early Greek poetic descriptions of eclipses, and the ninth paean of Pindar, addressed to the Thebans, takes an eclipse of the Sun as its theme, as follows:

> Beam of the Sun! O thou that seest from afar, what wilt thou be devising? O mother of mine eyes! O star supreme,

reft from us in the daytime! Why hast thou perplexed the power of man and the way of wisdom, by rushing forth on a darksome track?

Pindar then proceeds to speculate on the meaning of this omen. Although he prays, "Change this worldwide portent into some painless blessing for Thebes," he adds, "I in no wise lament whate'er I shall suffer with the rest." This strongly suggests that Pindar, who was a Theban, had himself recently witnessed a great eclipse at his hometown. The most probable date for the eclipse is April 30, 463 BC; modern calculations indicate that the eclipse was nearly total at Thebes.

The historian Thucydides comments on the frequency of eclipses during the Peloponnesian War, which began in 431 BC and lasted for 27 years. The most interesting of these was a solar eclipse that occurred in the summer of the first year of the war (calculated date August 3, 431 BC) and a lunar eclipse that took place in the summer of the 19th year (calculated date August 27, 413 BC). On the former occasion, "the Sun assumed the shape of a crescent and became full again, and during the eclipse some stars became visible" (a statement that agrees well with modern computations). The latter date had been selected by the Athenian commanders Nicias and Demosthenes for the departure of their armies from Syracuse. All preparations were ready, but the signal had not been given when the Moon was eclipsed. The Athenian soldiers and sailors clamoured against departure, and Nicias, in obedience to the soothsayers, resolved to remain thrice nine days. This delay enabled the Syracusans to capture or destroy the whole of the Athenian fleet and army.

August 15, 310 BC, is the date of a total eclipse of the Sun that is said to have been seen at sea by Agathocles and his men after they had escaped from Syracuse and were on their way to Africa. Diodorus, a historian of the 1st century BC, reports that, "On the next day [after the escape] there occurred such an eclipse of the Sun that utter darkness set in and the stars were seen everywhere." Modern computations of the eclipse track render it probable that Agathocles' ships passed along the north of Sicily during the course of the journey; the Sun would have only been partially obscured on the south side of the island.

Plutarch's interest in eclipses

In Plutarch's dialogue concerning the features of the Moon's disk, one of the characters, named Lucius, deduces from the phases of the Moon and the phenomenon of eclipses a similarity between the Earth and the Moon and illustrates his argument by means of a recent eclipse of the Sun, "which, beginning just after noon, showed us plainly many stars in all parts of the heavens, and produced a chill in the temperature like that of twilight." This eclipse has been identified with one that occurred on March 20, AD 71, which was total in Greece. Whether Plutarch is describing a real, and therefore datable, event or is merely basing his description on accounts written by earlier authors has been disputed, however. Later in the same dialogue, Lucius refers to a brightness that appears around the Moon's rim in total eclipses of the Sun. This is one of the earliest known allusions to the solar corona. Plutarch was unusually interested in eclipses, and his *Parallel Lives*, an account of the deeds and character of illustrious Greeks and Romans, contains many references to both lunar and solar eclipses of considerable historical importance. There also are frequent records of eclipses in other ancient Greek literature.

Roman. Roman history is less replete with references to eclipses than that of Greece, but there are several interesting references to these events in Roman writings. Some, like the total solar eclipse said by Dio Cassius, a Roman historian of the 3rd century AD, to have occurred at the time of the funeral of Agrippina, the mother of Nero, never took place. One that has attracted the attention of students of astronomy and of the Roman calendar alike is stated by Cicero to have occurred in what may have been the 350th year from the founding of Rome. He also says that it was described by the poet Quintus Ennius: "On the nones of June the Sun was covered by the Moon and night." This happening would appear to have been the total solar eclipse of June 21, 400 BC, which reached a total or almost total phase at Rome a few minutes after sunset. Its recorded date seems to show that in that year the calendar month of June began 16 days later than it did after the Julian reform. The eclipse of the Moon on June 21–22, 168 BC, has attracted much attention. The Romans were at that time at war with Macedonia, and Polybius says that this eclipse was interpreted as an omen of the eclipse of a king and thus encouraged the Romans and discouraged the Macedonians.

What may well be an indirect allusion to a total eclipse of the Sun that caused darkness at Rome is recorded by Livy for a time corresponding to 188–187 BC (the consulship of Valerius Messalla and Livius Salinator):

Before the new magistrates departed for their provinces, a three-day period of prayer was proclaimed in the name of the College of Decemvirs at all the street-corner shrines because in the daytime at the third hour darkness had covered everything.

The darkness took place some time after the election of the consuls (Ides of March), and, allowing for the confusion of the Roman calendar at this time, the total eclipse of July 17, 188 BC, would be the most satisfactory explanation for the unusual darkness. Since the Sun is not mentioned in the text, the phenomenon possibly occurred on a cloudy day. Two years earlier (190 BC), Livy records an eclipse as happening at the beginning of July. The calculated date, however, is March 14 in that year. Consequently, the Roman calendar in that year must have been as much as $3\frac{1}{2}$ months out of adjustment.

Medieval European. Following the close of the Classical Age, eclipses were in general only rarely recorded by European writers for several centuries. Not until after about AD 800 did eclipses and other celestial phenomena begin to be frequently reported again, especially in monastic chronicles. Hydatius, bishop of Chaves (in Portugal), was one of the few known chroniclers of the early Middle Ages. He seems to have had an unusual interest in eclipses, and he recounted the occurrence of five such events (involving both the Sun and the Moon) between AD 447 and 464. In each case, only brief details are given, and Hydatius gives the years of occurrence in terms of the Olympiads (*i.e.*, reckoning time from the first Olympic Games, in 776 BC). During the total lunar eclipse of March 2, AD 462 (this date is known to be accurate), the Moon is said to have been "turned into blood." Statements of this kind are common throughout the Middle Ages, presumably inspired by the Old Testament allusion in Joel (2:31). Similar descriptions, however, are occasionally found in non-Christian sources, as, for example, a Chinese one of AD 498.

Given below is a selection from the vast number of extant medieval European reports of eclipses. In many cases, the date is accurately recorded, but there also are frequent instances of chronological error.

English

An occultation of a bright star by the eclipsed Moon in AD 756 (actually the previous year) is the subject of an entry in the chronicle of Simeon of Durham, compiled some four centuries after the event:

Moreover, the Moon was covered with a blood-red color on the 8th day before the Kalends of December [*i.e.*, November 24] when 15 days old, that is, the Full Moon; and then the darkness gradually decreased and it returned to its original brightness. And remarkably indeed, a bright star following the Moon itself passed through it, and after the return to brightness it preceded the Moon by the same distance as it had followed the Moon before it was obscured.

The text gives no hint of the identity of the star. Modern computations show that the Moon was totally eclipsed on the evening of November 23, AD 755. During the closing stages of the eclipse, Jupiter would have been occulted by the Moon, as seen from England. This is an example of the care with which an observer who was not an astronomer could describe a compound astronomical event without having any real understanding of what was happening.

Byzantine

Several eclipses are recorded in Byzantine history, beginning in the 6th century AD. By far the most vivid account relates to the solar eclipse of December 22, AD 968. This was penned by the contemporary chronicler Leo the Deacon:

At the winter solstice there was an eclipse of the Sun such as has never happened before.... It occurred on the 22nd

day of the month of December, at the 4th hour of the day, the air being calm. Darkness fell upon the Earth and all the brighter stars revealed themselves. Everyone could see the disk of the Sun without brightness, deprived of light, and a certain dull and feeble glow, like a narrow headband, shining round the extreme parts of the edge of the disk. However, the Sun gradually going past the Moon (for this appeared covering it directly) sent out its original rays, and light filled the Earth again.

This is the earliest account of the solar corona that can be definitely linked to a datable eclipse. Although the appearance of the corona during totality is rather impressive, early descriptions of it are extremely rare. Possibly many ancient and medieval eyewitnesses were so terrified by the onset of sudden darkness that they failed to notice that the darkened Sun was surrounded by a diffuse envelope of light.

Italian

In a chronicle of the Norman rule in Sicily and southern Italy during the 11th century, Goffredo Malaterra records an eclipse of the Sun that, even though it caused alarm to some people, was evidently regarded by others as no more than a practical inconvenience:

[AD 1084] On the sixth day of the month of February between the sixth and ninth hours the Sun was obscured for the space of three hours; it was so great that any people who were working indoors could only continue if in the meantime they lit lamps. Indeed some people went from house to house to get lanterns or torches. Many were terrified.

This eclipse actually occurred on February 16, AD 1086. It was the only large eclipse visible in southern Italy for several years around this time; hence, the chronicler had mistaken both the year and day.

Medieval Islāmic. Like their Christian counterparts, medieval Islāmic chroniclers record a number of detailed and often vivid descriptions of eclipses. Usually the exact date of occurrence is given (on the lunar calendar). A graphic narrative of the total solar eclipse of June 20, AD 1061, is recorded by the Baghdad annalist Ibn al-Jawzī, who wrote approximately a century after the event:

On Wednesday, when two nights remained to the completion of the month Jumādā I [in AH 453], two hours after daybreak, the Sun was eclipsed totally. There was darkness and the birds fell whilst flying. The astrologers claimed that one-sixth of the Sun should have remained [uneclipsed] but nothing of it did so. The Sun reappeared after four hours and a fraction. The eclipse was not in the whole of the Sun in places other than Baghdad and its provinces.

The date corresponds exactly to June 20, AD 1061, on the morning of which there was a total eclipse of the Sun visible in Baghdad. The duration of totality is much exaggerated, but this is common in medieval accounts of eclipses. The phenomenon of birds falling from the sky at the onset of the total phase was also noticed in Europe during several eclipses in the Middle Ages.

References in Islāmic texts

Two independent accounts of the total solar eclipse of AD 1176 are recorded in contemporary Arab history. Ibn al-Athīr, who was age 16 at the time, described the event as follows:

In this year [AH 571] the Sun was eclipsed totally and the Earth was in darkness so that it was like a dark night and the stars appeared. That was the forenoon of Friday the 29th of the month Ramaḍān at Jaztrat Ibn 'Umar, when I was young and in the company of my arithmetic teacher. When I saw it I was very much afraid; I held on to him and my heart was strengthened. My teacher was learned about the stars and told me, "Now, you will see that all of this will go away," and it went quickly.

The date of the eclipse is given correctly apart from the weekday (actually Sunday) and is equivalent to April 11, AD 1176. Calculation shows that the whole of the Sun would have been obscured over a wide region around Jazīrat Ibn 'Umar (now Cizre in Turkey). Farther south, totality was also witnessed by Saladin and his army while crossing the Orontes River near Hamāh (in present-day Syria). The chronicler 'Imād al-Dīn, who was with Saladin at the time, noted that, "The Sun was eclipsed and it became dark in the daytime. People were frightened and stars appeared." As it happens, 'Imād al-Dīn dates the event one year too early (AH 570), but the only large eclipse visible in this region for several years occurred in AD 1176.

Lunar and solar eclipses are fairly frequently visible on the Earth's surface 15 days apart, and from time to time such a pair of eclipses may be seen from one and the same location. Such was the case in the summer of AD 1433, but this occurrence caused some surprise to the contemporary Cairo chronicler al-Maqrīzī:

On Wednesday the 28th of Shawwāl [*i.e.*, June 17], the Sun was eclipsed by about two-thirds in the sign of Cancer more than one hour after the afternoon prayer. The eclipse cleared at sunset. During the eclipse there was darkness and some stars appeared.... On Friday night the 14th of Dhu l-Qu'da [July 3], most of the Moon was eclipsed. It rose eclipsed from the eastern horizon. The eclipse cleared in the time of the nightfall prayer. This is a rarity—the occurrence of a lunar eclipse 15 days after a solar eclipse.

The loss of daylight produced by the solar eclipse is much exaggerated but otherwise the description is fairly careful.

Uses of eclipses for chronological purposes. Several examples of the value of eclipses in chronology have already been mentioned in passing. No one system of dating has been continuously in use since ancient times, although some, like the Olympiads, persisted for many centuries. Dates were frequently expressed in terms of a king's reign; years were also named after officials of whom lists have been preserved (the eponym canons mentioned above). In such cases, it is important to be able to equate certain specific years thus defined with years before the Christian Era (BC). This correspondence can be made whenever the date of an eclipse is given in an ancient record. In this regard, eclipses have distinct advantages over other celestial phenomena such as comets: in addition to being frequently recorded in history, their dates of occurrence can be calculated exactly.

Chinese chronology can be confirmed accurately by eclipses from the 8th century BC (during the Chou dynasty) onward. The *Ch'un-ch'iu* ("Spring and Autumn Annals"), a chronicle covering the period from 722 to 481 BC, notes the occurrence of 36 solar eclipses during this interval. This is the earliest surviving series of eclipse observations from any part of the world. The records give the date of each event in the following form: year of the ruler, lunar month, and day of the 60-day cycle. Three of the eclipses (occurring in 709, 601, and 549 BC) were described as total. As many as 32 of the eclipses cited in the *Ch'un-ch'iu* can be identified by modern calculations. Errors in the recorded lunar month (typically amounting to no more then a single month) are fairly common, but both the year and the recorded day of the sexagenary cycle are invariably correct.

Earliest surviving series of eclipse observations

The chronology of Ptolemy's canon list of kings, which gives the Babylonian series from 747 to 539 BC, the Persian series from 538 to 324 BC, the Alexandrian series from 323 to 30 BC, and the Roman series from 30 BC onward, is confirmed by eclipses. The eclipse of 763 BC, recorded in the Assyrian eponym canon, makes it possible to carry the chronology back with certainty through the period covered by that canon to 893 BC. Identifiable eclipses that were recorded under named Roman consuls extend back to 217 BC. The dated solar eclipse of Ennius (400 BC), the lunar eclipse seen at Pydna in Macedonia on June 21–22, 168 BC, and the solar eclipse recorded at Rome in 190 BC can be used to determine months in the Roman calendar in the natural year. Furthermore, eclipses occasionally help to fix the precise dates of a series of events, such as those associated with the Athenian disaster at Syracuse.

The late Babylonian astronomical texts occasionally mention major historical events, as, for example, the dates when Xerxes and Alexander the Great died. Most of these clay tablets, inscribed with a cuneiform script, are now found in the British Museum. The preserved texts are mainly in the form of day-to-day diaries of celestial observations and summary tables that abstract specific types of observation from the diaries. To illustrate the potential of this material for chronological purposes, the date of the death of Xerxes may be accurately fixed by reference to eclipses. On a tablet that lists lunar eclipses at 18-year intervals occurs the following brief announcement between

two eclipse records: "Month V, day 14 [?], Xerxes was murdered by his son." Unfortunately, the cuneiform sign for the day of the month is damaged, and a viable reading could be anything from 14 to 18. The year is missing, but it can be deduced from the 18-year sequence as 465 BC. This identification is confirmed by calculating the dates of the two eclipses stated to have occurred in the same year that Xerxes died. The first of these happened when the Moon was in the constellation of Sagittarius, while the second took place on the 14th day of the 8th lunar month. For many years both before and after 465 BC, no such combination of eclipses can be found; it occurs only in 465 BC itself. The dates deduced for the two eclipses are June 5 and November 30 of that year. Mention of an intercalary sixth month on the same tablet enables the date of the death of Xerxes to be fixed as some time between August 4 and 8 in 465 BC.

Uses of eclipses for astronomical purposes. *In ancient astronomy.* It is known from both Babylonian and Greek history that at least from the time of King Nabonassar (whose reign began in 747 BC), a dated canon of astronomical observations was preserved at Babylon. This included numerous eclipses of both the Sun and the Moon. Reference to the list of lunar eclipses would enable the Babylonian astronomers to determine accurately the intervals between such eclipses and must have facilitated the discovery of the 18-year cycle (more exactly the cycle of 6,585⅓ days that the 10th-century Greek lexicographer Suidas named the saros). This cycle is attested in Babylonian astronomy at a fairly early period. In contrast to lunar obscurations, the visibility of solar eclipses at a given place on the Earth's surface is complicated by geographic considerations. Hence, even a lengthy list of solar eclipse dates would be of limited value in deducing the saros.

Babylonian list of lunar eclipses

The surviving late Babylonian astronomical texts contain many examples of predictions of both lunar and solar eclipses using cycles. Comparison with modern computations shows that, although some predictions were successful, in other instances an eclipse was visible only elsewhere on the Earth's surface or did not occur at all. A theory based on a detailed knowledge of apparent lunar and solar motions is necessary to enable eclipses to be predicted accurately. Lunar eclipses indicate more accurately than any other phenomena the actual time when the Sun and the Moon are in opposition. From an early date the Babylonian astronomers must have deduced from lunar eclipses not only the mean interval between two conjunctions (closest apparent approaches) of the Sun and the Moon but also the principal inequality (change of speed) in the motion of the Moon and the similar inequality in the motion of the Earth (or, as according to their geocentric theory they conceived it, of the Sun). The Babylonians were able to define the periods of these inequalities (the cause of which lies in the ellipticities of the orbits), which astronomers refer to as the anomalistic month and year.

In the same way, since eclipses happen only when the Sun and the Moon are at the intersections of their orbital planes called nodes, and since the path of the shadow in a lunar eclipse depends on the position of the centre of the Sun in relation to the node, the Babylonians were also able to determine the position and motion of the nodes. By assuming, as is approximately true, that the saros of 6,585⅓ days contained an exact number: (1) of synodic months, or revolutions of the Moon measured from the Sun, (2) of anomalistic months, or revolutions of the Moon measured from its apogee or perigee (*i.e.*, from its farthest distance from and closest approach to the Earth), and (3) of draconic months, or revolutions of the Moon measured from its node, astronomers, perhaps as early as the 6th century BC, computed the relative motions of the Sun and the Moon, the lunar perigee and apogee, and the nodes. About 500 BC the Babylonian astronomer Nabu-rimmani, apparently from a more accurate study of eclipse observations, obtained improved values that: for the motion of the Moon relative to the Sun were 10″ of arc per annum too small; for the Moon's perigee motion 20″ of arc per annum too great; and for the motion of its node 5″ of arc too small. Still more accurate values were obtained by Kidinnu about 383 BC, from whom they passed to the Greek astronomer Hipparchus. In the system of Nabu-rimmani the distance of the Moon from its node was used for the prediction of the magnitude of lunar eclipses.

In modern astronomy. Ancient and medieval observations of eclipses are of the highest value for investigating long-term variations in the length of the day. Early investigators such as Edmond Halley deduced from eclipse observations that the Moon's motion was subject to an acceleration. However, not until 1939 was it demonstrated (by Harold Spencer Jones) that only part of this acceleration was real. The remainder was apparent and was a consequence of the practice of measuring time relative to a non-uniform unit—namely, the rotation of the Earth. Time determined in this way is termed Universal Time. For astronomical purposes, it is preferable to utilize an invariant time-frame such as Ephemeris Time.

Lunar and solar tidal friction, occurring especially in the seas and oceans of the Earth, is now known to be responsible for a gradual decrease in the terrestrial rate of rotation. Apart from slowing down the Earth's rotation, lunar tides produce a reciprocal effect on the Moon's motion, causing a gradual increase in the mean distance of the Moon from the Earth (at about 3.5 centimetres [1.4 inches] per year) and a consequent real retardation of its motion. Hence, the length of the month is slowly increasing. These changes in the Moon's orbit can now be accurately fixed by lunar laser ranging, and it seems likely that they have proceeded at an essentially constant rate for many centuries. The history of the Earth's rotation, however, is complicated by effects of nontidal origin, and in order to obtain maximum information it is necessary to utilize both modern and ancient observations. Telescopic observations reveal fluctuations in the length of the day on time scales as long as decades, and these fluctuations are mainly attributed to interactions between the fluid core of the Earth and the surrounding solid mantle. Ancient and medieval observations also suggest the presence of longer term variations, which could be produced by alterations in the moment of inertia of the Earth resulting from both the ongoing rise of land that was glaciated during the Pleistocene ice age and sea-level changes associated with the freezing and melting of polar ice.

Studying past variations in the Earth's rotation rate

Records of large solar eclipses preserved in literary and historical works have made an important contribution to the study of past variations in the Earth's rate of rotation. Nevertheless, the major contribution has come from the analysis of timings of lunar and solar eclipses by ancient Babylonian and medieval Arab astronomers. (Unfortunately, there are very few measurements of intermediate date.) Although many Babylonian texts are fragmentary, nearly 100 usable timings of eclipse contacts are accessible (including measurements at different phases of the same eclipse). These observations date primarily from between about 550 and 50 BC. By comparison, only a handful of similar Greek measurements are preserved, and these are far less precise. About 50 eclipse timings by medieval Arab astronomers are preserved; these are mainly contained in the Hakemite Tables compiled by Ibn Yūnus about AD 1005.

Tidal computations indicate a steady increase in the length of the mean solar day by about 1/40 second every millennium, with other nontidal causes producing additional smaller effects. Although this seemingly represents a minute change, the long time scale covered by ancient observations is an important asset. Approximately one million days—each marginally shorter than at present—have elapsed since the earliest reliable eclipse observations were made, about 700 BC. As a result, present-day computations of ancient eclipses that make no allowance for any increase in the length of the day may be as much as five or six hours ahead of the observed time of occurrence. In the case of total solar eclipses, the path of the Moon's shadow across the Earth's surface may appear to be displaced by thousands of kilometres.

The technique of using ancient observations to investigate changes in the rate of the Earth's rotation is well illustrated by a total solar eclipse observed by Babylonian astronomers on a date corresponding to April 15 in 136

BC. This event is recorded on two damaged tablets, a composite translation of which follows:

> At 24 degrees after sunrise, there was a solar eclipse beginning on the southwest side. After 18 degrees it became total such that there was complete night. Venus, Mercury, and the normal stars were visible. Jupiter and Mars, which were in their period of disappearance, were visible in that eclipse. [The shadow] moved from southwest to northeast. [Time interval of] 35 degrees for obscuration and clearing up.

This is an exceptionally fine account of a total solar eclipse and is by far the best preserved from the ancient world. As will be seen, the Babylonians were able to detect a number of stars, as well as four planets, during the few minutes of darkness. Modern calculations confirm that Jupiter and Mars were too near the Sun to be observed under normal circumstances; Jupiter was very close to the solar disk.

Time intervals were expressed by the Babylonians in degrees, each equivalent to 4 minutes of time. Hence the eclipse is recorded as beginning 96 minutes after sunrise (or about 7:10 AM), becoming total 72 minutes later and lasting from start to finish for 140 minutes. Computations that make no allowance for changes in the length of the day suggest that this eclipse was barely visible at Babylon, with as little as 15 percent of the Sun being covered. Furthermore, the computed time of onset is around noon rather than in the early morning. In order to best comply with the record, it is necessary to assume that the length of the day has increased by about $^1/_{20}$ second in the intervening two millennia.

Numerous eclipses of both the Sun and the Moon were timed by the Babylonian astronomers with similar care, and analysis of the available records closely confirms the above result for the change in the length of the day. Presumably some kind of clepsydra, or water clock, was used to measure time intervals. Although such a device is likely to have been of low precision, many eclipse observations were made fairly close to the reference moments of sunrise or sunset. Hence, the measured intervals would be so short that clock errors may be presumed to be small.

The latest known Babylonian observations date from about 50 BC. After this date, eclipse measurements of comparable precision—by Arab astronomers—are not found until AD 800. The following observations of the lunar eclipse of September 17, AD 1019, made by al-Bīrūnī at Ghazna (now Ghaznī, Afghanistan) attest to the quality of these more recent data:

> When I observed it, the altitude of Capella above the eastern horizon was slightly less than 60 degrees when the cut at the edge of the Full Moon had become visible; the altitude of Sirius was [then] 17 degrees, that of Procyon was 22 degrees and that of Aldebaran was 63 degrees, where all altitudes are measured from the eastern horizon.

All of these various measurements are in agreement that the eclipse began at around 2:15 AM, but calculations that make no allowance for any change in the length of the day indicate a time approximately $^1/_2$ hour later.

Combining the various results obtained from analysis of ancient and medieval data, it is possible to show that over the last 1,000 years the average rate of increase in the length of the day was only about two-thirds of what it was in the previous millennium. This emphasizes the importance of nontidal effects in producing changes in the rate of the Earth's rotation period. In sum, the history of the Earth's rotation is extremely complex. (J.H./F.R.S.)

SAID, "Non-tidal Changes in the Earth's Rate of Rotation as Deduced from Medieval Eclipse Observations," *Astronomy and Astrophysics,* 215(1):181–189 (1989). Catalogs of eclipse data include TH. RITTER VON OPPOLZER, *Canon of Eclipses* (1962; originally published in German, 1887), astronomical data of all solar eclipses between 1207 BC and AD 2161 and eclipses of the Moon from 1206 BC to AD 2163, with maps of the central lines of the solar eclipses over the Earth; GEORGE VAN DEN BERGH, *Eclipses in the Second Millennium B.C. (−1600 to −1207)* (1954), a demonstration of a method for computing each of these eclipses with simple arithmetic, and *Periodicity and Variation of Solar (and Lunar) Eclipses* (1955; originally published in Dutch, 1951), an arrangement of all the eclipses in Oppolzer's *Canon* into the saros and the inex periods in a newly developed panorama; ROBERT R. NEWTON, *Ancient Astronomical Observations and the Accelerations of the Earth and Moon* (1970), and *Medieval Chronicles and the Rotation of the Earth* (1972); and HERMANN MUCKE and JEAN MEEUS, *Canon of Solar Eclipses −2003 to +2526* (1983), and *Canon of Lunar Eclipses −2002 to +2526,* 2nd ed. (1983), more accurate data and maps of central lines over the Earth of all solar and lunar eclipses over 4,500 years. JOSEPH NEEDHAM, *Science and Civilisation in China,* vol. 3, *Mathematics and the Sciences of the Heavens and the Earth* (1959), includes a discussion of eclipses placed in the context of Chinese astronomy with extensive references to original literature. BERNARD LOVELL (ed.), *Astronomy,* 2 vol. (1970), contains discourses in the physical sciences from 1851 to 1939, a large number of which are devoted to solar eclipses. (J.H./F.R.S.)

Economic Growth and Planning

Economic growth involves increases over time in the volume of a country's per capita gross national product (GNP) of goods and services. Such continuing increases can raise average living standards substantially and provide a stronger base for other policy objectives such as national defense, various kinds of capital investments, or public welfare services. It is only in the last two centuries that continued growth in living standards has been realized for a number of now-developed countries, and this process has broadened in the 20th century to include a number of developing countries. However, the fairly steady expansion in the third quarter of the 20th century gave way to a period of slower and more erratic growth for both high- and low-income countries, while some of the economically poorest countries were thus far unable to establish a self-sustaining pattern of development. It also became increasingly evident that there were serious environmental problems associated with some types of growth in production.

This article examines the record of economic growth and development, some explanations for the changes involved, and the attempts by governments to plan these changes. Five major issues are involved. The first is why economic growth occurs more quickly in some countries and periods than in others. It is the increase in the size and quality of the factors of production that underlies growth, but certain forces—innovations and entrepreneurship, the part played by governments, and the role of investment as distinct from consumption—deserve special attention. A variety of models of economic growth give expression to the understanding of these forces. Increasing attention has been paid in these models and in policy to the international aspects of growth. This trend is partly a reflection of the growing internationalization of economic activity. It also reflects a number of potentially destabilizing changes in the international economy that became evident during the 1970s. While the precise nature of their effects is open to debate, among these changes should be noted the transition to more flexible exchange rates, the supply shocks in petroleum and other products, the growth of international debt, and the development of several major centres of economic power.

A second issue is the challenges facing the low-income countries, namely, to move from subsistence levels of per capita income to a level that would generate self-sustaining growth and also to reduce the gap between themselves and the higher-income countries. Differences among the lower-income countries warn against making sweeping generalizations on the development process, but three topics have attracted much attention. One is how far existing private and public organizations must be changed so as to institutionalize development. A second is the view that, particularly for manufactures and for smaller markets, reliance on import substitution should give way fairly quickly to export development. The third is the impact of population growth on both development and living standards.

The uneven patterns of growth and development have led to many strains. In the case of higher-income countries these have appeared particularly as declines and failures in some of their older industries in the face of increased competition among themselves and with the newly industrializing countries. In many developing countries there have been repeated calls for a new organization of world institutions geared to a more equitable distribution of wealth.

A third issue, productivity, is central to changes in living standards and to the analysis of international competitiveness. Productivity is the ratio of what is produced to what is required to produce it, a ratio beset with measurement problems. Studies of the reasons for the growth of productivity have focused on technological change and on the accumulation of physical and human capital. However, a considerable number of social, political, and economic issues appear to be involved in the striking differences in rates of change in productivity among countries. Nor is there agreement on the reasons for and significance of the marked slowing of productivity growth in many countries during the 1970s and 1980s. Some economists see merely passing factors at work, while others predict continuing problems for developed countries and the international economy generally.

A fourth major issue is the attempt to maintain growth and increase development through economic planning. Such planning has other objectives as well, such as regional development, constraining wage–price inflation, and easing the adjustment between declining and growing sectors. Planning became a widespread phenomenon during and just after World War II and was given further emphasis in many newly independent countries that were industrializing. The degree of detail and the methods used in planning range from heavily centralized direction and substantial public ownership to attempts simply to trim the overall balance of supply and demand, with different degrees of attention to industrial strategies along the way. Beginning in the 1970s the emphasis shifted to more decentralized planning, with deregulation and privatization of industry as two aspects of this process.

Underlying economic growth and planning is a fifth issue, the attempt to predict economic activity. Modern forecasting involves a variety of computer-based techniques at the level of the firm, the country, and the international economy. The accuracy of forecasting has been reduced by increased uncertainty in the global and national economies since the early 1970s. (A.E.Sa.)

This article is divided into the following sections:

How economies grow

Growth can best be described as a process of transformation. Whether one examines an economy that is already modern and industrialized or an economy at an earlier stage of development, one finds that the process of growth is uneven and unbalanced. Economic historians have attempted to develop a theory of stages through which each economy must pass as it grows. Early writers, given to metaphor, often stressed the resemblance between the evolutionary character of economic development and human life—*e.g.*, growth, maturity, and decadence. Later writers, such as the Australian economist Colin Clark, have stressed the dominance of different sectors of an economy at different stages of its development and modernization. For Clark, development is a process of successive domination by primary (agriculture), secondary (manufacturing), and tertiary (trade and service) production. For the American economist W.W. Rostow, growth proceeds from a traditional society to a transitional one (in which the foundations for growth are developed), to the "take-off" society (in which development accelerates), to the mature society. Various theories have been advanced to explain the movement from one stage to the next. Entrepreneurship and investment are the two factors most often singled out as critical.

Stages of growth

Economic growth is usually distinguished from economic development, the latter term being restricted to economies that are close to the subsistence level. The term economic growth is applied to economies already experiencing rising per capita incomes. In Rostow's phraseology economic growth begins somewhere between the stage of take-off and the stage of maturity; or in Clark's terms, between the stage dominated by primary and the stage dominated by secondary production. The most striking aspect in such development is generally the enormous decrease in the proportion of the labour force employed in agriculture. There are other aspects of growth. The decline in agriculture and the rise of industry and services has led to concentration of the population in cities, first in what has come to be described as the "core city" and later in the suburbs. In earlier years public utility investment (including investment in transportation) was more important than manufacturing investment, but in the course of growth this relationship was reversed. There has also been a rise in the importance of durable consumer goods in total output. In the U.S. experience, the rate of growth of capital goods production at first exceeded the rate of growth of total output, but later this too was reversed. Likewise, business construction or plant expenditures loomed large in the earlier period as an object of business investment compared to the recent era. Whether other countries will go through the same experience at similar stages in their growth remains to be seen.

National comparisons

Comparative growth rates for a group of developed countries show how uneven the process of growth can be. Partly this unevenness reflects the extraordinary nature of the 1913–50 period, which included two major wars and a severe and prolonged depression. There are sizable differences, however, in the growth rates of the various countries as between the 1870–1913 and 1950–73 periods and the period since 1973. For the most part, these differences indicate an acceleration in rates of growth from the first to the second period and a marked slowdown in growth rates from the second to the current period. Many writers have attributed this to the more rapid growth of business investment during the middle of the three periods.

The relatively high rates of growth for West Germany, Japan, and Italy in the post-World War II period have stimulated a good deal of discussion. It is often argued that "late starters" can grow faster because they can borrow advanced technology from the early starters. In this way they leapfrog some of the stages of development that the early starters were forced to move through. This argument is nothing more than the assertion that late starters will grow rapidly during the period when they are modernizing. Italy did not succeed in growing rapidly and thereby modernizing until after World War II. Together with Japan and Germany it also experienced a large amount of war damage. This has an effect similar to starting late, since recovery from war entails building a stock of capital that will, other things being equal, embody the most advanced technology and therefore be more productive and allow faster growth. The other part of this argument is the assertion that early starters are actually deterred from introducing on a broad front the new technology they themselves have developed. For example, firms in a country that industrialized early may be inhibited from introducing a more modern and efficient means of transportation on a broad scale because there is no guarantee that other firms handling the ancillary loading and unloading tasks will also modernize to make the change profitable.

Related to this is the problem of whether or not per capita income levels and their rates of growth in developed economies will eventually converge or diverge. For example, as per capita incomes of fast growers like the Italians and Japanese approach those of economies that developed earlier, such as the American and British, will the growth rates of the former slow down? Economists who answer in the affirmative stress the similarities in the changing patterns of demand as per capita income rises. This emphasis in turn implies that there is less and less chance to borrow technology from the industrial leaders as the income levels of the late starters approach those of the more affluent. Moreover, rising per capita incomes in an affluent society usually are accompanied by a shift in demand toward services. Therefore, so this argument goes, differences in income levels and growth rates between countries should eventually narrow because of the low growth in productivity in the service sector. The evidence is inconclusive. On the one hand, growth is a function of something more than the ability to borrow the latest technology; on the other hand, it is not clear that productivity must always grow at a slower rate in the service industries.

A rapidly increasing population is not clearly either an advantage or a disadvantage to economic growth. The American Simon Kuznets and other investigators have found little association between rates of population growth and rates of growth of GNP per capita. Some of the fastest growing economies have been those with stable populations. And in the United States, where the rate of growth of population has shown a downward historical trend, the

rate of growth of GNP per capita has increased over the last century and a half. Another finding by Kuznets is that while GNP per capita in 1960 was substantially higher in the United States than in any European country, there was no significant difference in the per capita growth rates of all these countries over the period 1840 to 1960 as a whole. The conclusion is that the United States started from a higher per capita base; this may have been the result of its superior natural resources, especially its fertile agricultural land.

THE ANALYSIS OF GROWTH

Capital and labour

To explain why some countries grow more rapidly than others or why a country may grow more rapidly during one period of history than another, economists have found it convenient to think in terms of a "production function." This is a mathematical way of relating some measure of output, such as GNP, to the inputs required to produce it. For example, it is possible to relate GNP to the size of the labour force measured in man-hours, to capital stock measured in dollars, and to various other inputs that are considered important. An equation can be written that states that the rate of growth of GNP depends upon the rates of growth of the labour force, the capital stock, and other variables. A common procedure is to assume that the influence of the separate inputs is additive—*i.e.*, that the increase in the growth of output caused by increasing the rate of growth of, say, capital is independent of the rate of growth of the labour force. This is the starting point of a great deal of current empirical work that attempts to quantify the importance of different inputs.

Under certain assumptions, some reasonable and some patently false, it is possible to conclude that what labour and capital receive in the form of wages, profits, and interest is a fair measure of what they contribute to the productive process. Thus in the United States in the period following World War II the share of output going to labour was approximately 79 percent, while the share of output distributed as "profits" was 21 percent. If we assume that these proportions determine how much we should weight the rate of growth of the labour force and of capital respectively in determining their contribution to the rate of growth of output, we must conclude that the relative contribution of capital is slight. Alternatively, we may say that some given percentage increase in the rate of growth of the labour force will have a much larger influence on the rate of growth of output than the same percentage increase in the rate of growth of capital. This is a puzzling result and can be traced to the assumption that the influence of separate inputs is additive.

Quality improvements in the inputs. Much work has been done in an effort to measure the inputs in the productive process more accurately by taking account of improvements in the quality of both labour and capital over time. For example, it has been argued that the amount of a worker's time spent on his formal education is positively related to the income he receives and to his productive contribution. Measuring the number of man-hours worked from one period to the next will not give a true picture of the increase in labour input if the average amount of education received by workers is changing. Man-hour units must be converted to "efficiency" units. Thus if a labour force of 100 workers in the first year all had an eighth-grade education, while 20 years later each member had a 10th-grade education, then measured in efficiency units the labour force had grown. If the length of time spent on formal education increases over time, then the growth of the labour input will be larger if measured in efficiency units. There is, thus, an element of capital in the labour force.

Investment in human capital

Examples of investment in human capital are expenditures on health and on all types of education, including on-the-job training. Expenditures of this sort increase the quality of the labour force and its ability to perform productive tasks. Many economists have argued that technological progress is really nothing but quality improvements in human beings. Some economists take an even broader view and speak of the "production of knowledge" as the clue to technological progress. The production of knowledge is a broad category including outlays on all forms of education, on basic research, and on the more applied type of research associated especially with industry. It is argued that fast-growing industries tend to be those having a high research and development component in their total costs. In addition, firms within an industry that have large research and development budgets tend to experience the most rapid technological progress. The argument is that technical change and improvements must originate in inventions that lead to innovations in the products produced or in the processes whereby existing products are manufactured.

A similar argument applies to the size of the capital stock. It can be maintained that design improvements increase the efficiency of capital goods so that a dollar's worth of machinery purchased today may be much more efficient than a dollar's worth of depreciated machinery purchased yesterday. The rate of growth of the capital stock measured so as to take account of quality improvements will be greater than the rate of growth of the capital stock measured in a way that neglects the differences between "vintages."

Some economists have stressed "economies of scale." For example, if an increase in the use of capital and labour leads to a greater than proportionate increase in output, this is said to result from economies of scale. Economies of scale may arise because an expansion of the market justifies a radical change in productive techniques. These new techniques may be so much more efficient that the returns in the way of increased output are much greater proportionately than the increase in inputs.

Another source of growth and of technical progress in particular has been seen in shifts of demand from low productivity sectors to high productivity sectors, thus causing resources to be reallocated. The most notable movement has been the shift of resources, especially labour, out of agriculture—a traditionally low-productivity sector. Such shifts act to increase the rate of growth of output in ways that cannot be accounted for by simply measuring growth in total inputs. Historically, the allocation of both capital and labour have shifted during the growth process from low productivity sectors to high ones, causing the rate of growth of output to exceed the weighted average of the rates of growth of total inputs.

Entrepreneurship. This historical fact points to an element that has received little attention so far: the influence of entrepreneurship. If the allocation of resources changes during the course of growth and development, it does so under the leadership of an entrepreneurial class. The quality of entrepreneurship is seen by many economists as an important explanation of differences in the rate of technical progress between countries. Decisions must be made somewhere along the line as to whether a new product or process will be introduced. It has been argued that two countries undertaking similar amounts of investment leading to more or less identical rates of growth in the capital stock will not necessarily show the same rate of technical progress. In one country entrepreneurs may be undertaking enterprise investment that has as its aim the introduction of the most advanced types of production techniques, those that will lead to a rapid growth of labour productivity. In the other, because of hesitation or ignorance, the investment program may lead only to marginal changes in productive processes; the resulting growth in labour productivity and GNP will be small. For example, much has been said since World War II about the more aggressive nature of German businessmen as compared to their English counterparts. The emphasis on the role of the entrepreneur in economic growth stems from the theoretical work of the economist Joseph A. Schumpeter, but many others have echoed it.

Arguments about the significance of capital investment

The play of influences. Much thinking assumes, then, that contributions to output from growth of individual inputs are independent of one another. This assumption allows many growth theorists to conclude that capital investment is relatively unimportant as a growth factor. If there is interaction between the rates of growth of the different inputs, however, then it is possible to draw different conclusions. For example, over time there are likely

to be improvements in the quality of capital goods. A machine that requires so much steel and so much labour to manufacture may be twice as productive as an older machine that required the same amount of raw materials and labour in its manufacture. Thus the rate of growth of technical progress and the rate of growth of the capital stock measured in natural units interact. Furthermore, the interaction between technical progress and capital formation is not necessarily in one direction. New knowledge opens up new production possibilities and gives rise to potential increases in technical progress and profits. Or the better educated the labour force, the more adaptable it is likely to be and therefore the better able to cope with new production techniques. At the same time, the higher the rate of growth of capital, the higher will be the growth of incomes and therefore the demand for education. The fact that much of the overall growth of technical progress stems from the transfer of resources and the positive association between the rate of transfer of resources and the rate of growth of the capital stock is another example of interdependence or complementarity between the growth of the inputs. But, again, capital investment undertaken to develop new lines of production will also be dependent on technological progress going on in those areas.

Conventional marginal productivity doctrine argues that as an input such as capital rises relative to labour, the additional output or marginal product that can be attributed to this extra amount of capital will be less than what a unit of capital on the average had been producing before. Marginal productivity doctrine also assumes that each unit of capital is identical with the next. This assumption is the basis for the argument that as more units of capital are utilized in production with a given amount of labour, it will push down the former's marginal product. There is the possibility, however, that additional units of capital may enhance the productivity of existing units: for example, an increase in the amount of capital resources devoted to the development of transportation and distribution may raise the productivity of capital employed, say, in manufacturing. The development of this kind of social overhead capital is certainly a prerequisite for a high return to capital in manufacturing, wholesaling, and retailing.

The analysis can be carried back one more step, to the basic determinants of growth. Economists ask why it is that capital, labour, or technical progress has grown more rapidly in one economy than in another or at one time than at another. Historically, the transition from a subsistence-level, underdeveloped state to a higher-level, developed one has been accompanied by a decline in the death rate followed by a decline in the birth rate. This has the effect of first speeding up the rate of growth of the population and labour force and then reducing it as birth rates fall. Migration can alter this picture, often unpredictably. In the United States, for example, the rate of growth of the population and labour force during the 19th and early 20th centuries was higher than in most other developed countries, mainly because of high rates of immigration. From 1840 to 1930, the native-born U.S. population increased about 600 percent, while the number of those of foreign birth increased 1,300 percent.

The role of government. The differences in rates of growth are often attributed to two factors: government and entrepreneurship. The two are not mutually exclusive. In the early stages of sustained growth, government has often provided the incentives for entrepreneurship to take hold. In some economies the development of transportation, power, and other utilities has been carried out by the government. In others the government has offered financial inducements and subsidies. The land given U.S. railroad developers in the second half of the 19th century is a notable example of the latter. Another important role governments have played in the early stages is to help establish the sort of capital and money markets in which lenders could have confidence. Without financial intermediaries acting as brokers between lenders and business borrowers, it is difficult to envisage economic growth taking place on a sustained and rapid basis.

Government measures in the 19th century

In the 19th century most liberal thinkers held that the main role for government in a developed capitalist system was that of a policeman: to preserve law and order, uphold the sanctity of private property, and give business as much freedom as possible. The Great Depression of the 1930s persuaded many that a laissez-faire system did not automatically provide the necessary incentives to the innovation and risk bearing essential for economic growth. This led to a good deal of writing on the role that governments might play in stimulating growth. Economists have argued that, at the very least, governments can undertake to prevent serious and prolonged recessions. Only in this way can a general business psychology be developed that assumes growth to be the natural course of things, so that investment programs will pay off.

Growth theorists since World War II have gone further, arguing that it is not enough simply to achieve full employment periodically. Some maintain that it is necessary to maintain full employment over an extended period of time if high growth is to result. This argument relates to the earlier point that two economies may experience the same rate of growth of capital but that overall growth and technical progress will proceed at a much more rapid rate in one than in the other because of differences in the quality of new capital goods produced. The term enterprise investment has been used to describe the kind of capital formation that involves innovations and that by building ahead of demand generates rapid rates of growth of productivity or technical progress. But to get such growth, it has been argued, an economy must be run "flat out," at full speed. While this has been subject to some dispute, there is a fairly general consensus that growth will be faster when unemployment fluctuates within a narrow range and at low levels.

Government intervention in expenditure

A variation on this argument is the question of how a government may intervene to determine the distribution of output between those types of expenditure that contribute to growth and those that lead to the immediate satisfaction of consumer demand. Here the choice lies between business investment, research, and education on the one hand and consumption on the other. The larger the first three, the more rapid will be the rate of growth. Governments giving a high priority to growth have various means at their disposal for influencing it. Consumption can and has been constrained through increases in income tax rates. The same is true of other tax rates such as the property tax—the chief revenue source for primary and secondary education in the United States. Tax credit for research and development expenditures is a common method for encouraging business outlays that may lead to innovations. The same method has been used to stimulate business investment outlays. "Easy money" policies on the part of the central bank, whereby the cost of borrowed funds and their availability are indirectly regulated in such a way as to encourage business borrowing, may lead to higher levels of real investment.

The true cost of stimulating growth will always be a temporary cut in current consumption. Only in the future can the economic benefits of the higher investment be realized. By the same token, current consumption can always be enlarged by a neglect of the future. It is even possible for current production to be so biased toward the satisfaction of immediate needs that the productive capacity of an economy slowly declines as capital goods are not replaced. Between the extremes of total neglect of future generations and the paring down of current consumption to a bare subsistence minimum lie an infinite number of possibilities.

THE SOCIAL COST OF GROWTH

The belief that governments should have a large say in choosing the "right" rate of growth has also led some writers to challenge the social and economic value of economic growth in an advanced industrial society. They attribute to growth such undesirable side effects of industrialization as traffic congestion, the increasing pollution of air and water, the despoiling of the landscape, and a general decline in man's ability to enjoy the "real" amenities of life. As has been seen, growth is really a transformation whereby certain industries experience a rise in importance followed by an eventual decline as the market for their output be-

comes relatively saturated. Demand, relatively speaking, moves on to other types of industries and products. All of this naturally implies a reallocation of resources over time. The faster these resources move, other things being equal, the more rapidly can growth and transformation proceed. The argument can be recast in terms of this transformation. A slower rate of growth in per capita consumption will slow down the rate of transfer of resources, but it may also result in a more livable environment. The rate of growth of individual welfare, so measured as to take into account non-consumable amenities, may even be increased. Some argue that in a growth-oriented society wants are created faster than the industrial machine can satisfy them, so that people are more dissatisfied and insecure than they would be if growth were not given such a high value. It is held by some critics that, in modern industrial society, consumption exists for the sake of justifying production rather than production being carried out to satisfy consumer desires. These arguments are a powerful challenge to those who see growth as the most important economic goal of a modern society.

THEORIES OF GROWTH

In discussing theories of growth a distinction must be made between theories designed to explain growth (or the lack of growth) in countries that are already developed and those concerned with countries trapped in circumstances of poverty. Most of what follows will be confined to the former.

The savings–investment equation

As the British economist John Maynard Keynes pointed out in the 1930s, saving and investment are not usually done by the same persons. The desire to save does not necessarily generate investment. If savers attempt to save a larger share of their income than before (thereby consuming less) and if this is not matched by an equal increase in the desire of others to invest, total spending will decline. A natural reaction on the part of business will be to cut back on production, thereby reducing incomes earned in production. The final effect may be a cumulative movement downward as total demand becomes insufficient to employ all of the labour force. This break in the circular flow of income and expenditure suggests the possibility of a capitalist economy alternately experiencing periods of prolonged and severe unemployment (when desired savings at full employment exceed what the economy wishes to invest at full employment) and periods of serious inflation (when the inequality is reversed). This situation had not been the case historically for developed economies until the early 1970s. In the following discussion, some attention will be paid to the ways in which the various theories of growth account for this important historical fact.

Role of the entrepreneur. Modern growth theory can be said to have started with Joseph A. Schumpeter. Unlike most Keynesian or pre-Keynesian theorists, Schumpeter laid primary stress on the role of the entrepreneur, or businessman. It was the quality of his performance that determined whether capital would grow rapidly or slowly and whether this growth would involve innovation and change—*i.e.*, the development of new products and new productive techniques. Differences in growth rates between countries and between different periods in any one country could be traced largely to the quality of entrepreneurship. The latter in turn reflected certain historical and cultural values carried by the business class. Schumpeter also attributed much of the growth of technical progress and of the supply of labour to the entrepreneur. Thus, in more modern terminology, Schumpeter's explanation of why demand and supply have grown more or less at the same rate would be that supply adjusted to demand while demand in turn reflected the activities and investments of the entrepreneur.

Schumpeter believed that capitalism by its very success "sows the seeds of its own destruction." The American economist Alvin H. Hansen argued in the late 1930s that capitalism was in trouble in the United States for other reasons. According to Hansen, the closing of the geographic frontier, the decline in the rate of population growth, and the capital-saving character of recent innovations had all worked to increase the likelihood of stagnation by reducing the need for investment. The savings available in a mature economy would tend to exceed the amount that the economy would want to invest (at levels of full employment) and by progressively larger amounts as time went on. This condition naturally would lead to increasing rates of unemployment as the discrepancy between demand and potential output widened. Hansen's views were very much coloured by the economic conditions of the 1930s. The record of the three decades after World War II did much to overcome the pessimism generated by the Great Depression.

The role of investment. In Keynes's *General Theory*, investment played a key role in that it was presented as the most important factor governing the level of spending in an economy, despite the fact that it typically was only one-fifth to one-sixth of total spending. This paradox can be understood in terms of a concept also developed in the 1930s, the multiplier. The multiplier was the amount by which a change in investment would be multiplied in achieving its final effect on incomes or expenditures. If, for example, investment increases by $10, the extra $10 of expenditures will generate, assuming unemployed resources, an extra $10 of production and subsequently incomes in the form of wages and profit. This increase, however, is hardly the end of the matter since most of the additional incomes earned will be respent on consumer goods. If nine-tenths of any change in income is spent on consumer goods and one-tenth is saved, consumption will increase by $9. But again, one person's expenditures are another person's income, so that incomes now rise by $9 of which $8.1 is respent on consumer goods. The process continues until expenditures, incomes, and production have increased by $100, of which $90 is consumption and $10 the original change in investment. In this case the multiplier is 10.

The negative aspects of investment

But investment may be a source of instability if it is not maintained at a rate sufficient to stimulate demand for the production it is creating. Is there any guarantee that supply or productive capacity will grow at the same rate as demand so that neither excess capacity nor excess demand results? The British economist R.F. Harrod and the American economist E.D. Domar put this question in a very simple mathematical form. In their equations, the rate of growth of supply (*i.e.*, the production function as defined above) is equal to the rate of growth of capital stock. Through investment this capital stock is augmented. The rate of growth of demand depends upon the rate of growth of investment or, more correctly, upon the rate of growth of nonconsumption expenditures. Thus investment affects both demand and supply. But the Harrod–Domar analysis still did not answer the question of what kept the system from becoming increasingly unstable.

Demand and supply. Much contemporary growth theory can be viewed as an attempt to develop a theoretical model that would bring the rate of growth of demand and the rate of growth of supply into line, since a model implying that capitalist systems are inherently unstable would not correspond to the historical facts. Models of growth may be classified according to whether they emphasize adjustments in demand (supply-determined models) or adjustments in supply (demand-determined models). One of the better-known examples of the supply-determined model was developed by the British economist J.R. Hicks. Hicks assumed that the spending propensities of consumers and investors were such as to cause demand to grow at a rate in excess of the rate of growth of maximum output. This assumption meant that during any "boom" the economy would eventually run into a "ceiling" that, while also moving upward, was moving less rapidly than demand. The long-run rate of growth of the economy would be determined by the rate of ascent of the ceiling, which in turn would depend upon supply factors such as the rate of growth of the labour force and the rate of growth of technical progress or productivity. If for some reason these were to grow more rapidly, then output would also grow more rapidly as demand adjusted upward to the more rapid growth of supply.

An example of a demand-determined model of growth is one developed by the American economist J.S. Duesen-

berry. In the Duesenberry model, spending propensities of consumers and investors are such as to generate steady growth in demand. Assume that instead of spending nine-tenths of any change in income on consumer goods, as in the multiplier example above, they choose to spend 0.95. This increase will cause the rate of growth of demand to increase. The question is whether it will also cause the rate of growth of production to increase or whether it will merely result in price increases. If productivity or technical progress responds to a higher rate of growth of demand, as Duesenberry assumes, then production can grow more rapidly. Although in both the Hicks and Duesenberry models demand and supply grow at the same rate, the adjustment mechanisms are entirely different. In the Duesenberry model supply adjusts to demand; in the Hicks model demand adjusts to supply.

Other models of growth also illustrate this distinction between demand-determined and supply-determined growth. The British economist N. Kaldor assumed that there is a mechanism at work generating full employment. Simply stated, in his model an inadequate rate of investment will be offset by shifts in the distribution of income between profits and wages, which will cause consumption to change in a compensating manner so that overall demand is unchanged. While there are important differences between the Hicks and Kaldor models, both can be described as models of supply-determined growth.

Another model of supply-determined growth is that implicit in the traditional neoclassical analysis. The mechanism that adjusts demand to growing supply is the price mechanism, or Adam Smith's "invisible hand" of the market. This type of model assumes a world devoid of monopoly and uncertainty, in which the markets for capital goods and labour are free to adjust quickly so that "markets are always cleared" in the very short run.

Government intervention in demand and supply

A final example of a model of growth that illustrates the problem of adjustment between supply and demand is to be found in the work of the Dutch economist Jan Tinbergen and his followers. In contrast to neoclassical growth models where the market brings about an adjustment of demand to supply, the "target-instrument" models of Tinbergen assume that the government (as in The Netherlands and other European countries) undertakes to regulate demand and supply in an effort to achieve certain targets such as full employment or a predetermined rate of growth. For example, economists are expected to provide the fiscal authorities with a model that approximates the working of the economy and that indicates what will happen if the government, say, does not change its tax and spending programs in the coming period. These forecasts are appraised in terms of what the authorities consider desirable as a matter of social and economic policy. If it appears that unemployment will be too high and the rate of growth too low, the authorities take countermeasures. The government may, for example, cut taxes on corporate profits in order to stimulate investment. If investment is excessive and there is danger of inflation, the government may take other measures to reduce aggregate demand such as cutting its expenditures. This type of planning procedure has been tried with varying degrees of success. Sweden and The Netherlands are prominent examples of attempts to offset fluctuations in private spending so as to realize full employment and growth. It should be noted that these models do not fit neatly into the demand-determined or supply-determined classification. In the example just given, both the rate of growth of demand and the rate of growth of supply are effectively determined by the fiscal authorities.

Economic stagnation. The rise in unemployment rates and the slowdown in growth rates of GNP and per capita incomes throughout the capitalist world beginning in the early 1970s is clearly a case where demand and supply did not grow at similar rates. Many economists turned their attention to developing theories to explain this prolonged period of stagnation. A common theme in much of their work was the adverse effects of high unemployment and low utilization of the capital stock on investment and, therefore, on productivity growth.

The high unemployment rates for labour and capital are initially traced to policies restricting aggregate demand that were pursued by monetary and fiscal authorities from the first half of the 1970s. This policy response was widely interpreted by economists as an effort by the authorities to reduce inflation rates that had begun to accelerate in the latter 1960s. The continued use of restrictive policies is then related to fear on the part of the authorities that any attempt to restimulate their economies would merely bring back inflation.

Tighter labour markets resulting from any such stimulative policies are seen to increase the bargaining power of labour, thereby leading to larger wage demands and settlements that in turn feed into prices, causing price inflation to accelerate. This leads to yet higher wage demands in order to protect real wages and thus an explosive wage–price spiral. In addition, more stimulative aggregate demand policies are perceived to result in balance of payments difficulties at existing exchange rates. But any attempt to avoid larger payments deficits by reducing the exchange rate leads to the "importation" of inflation through higher prices of imported goods. The result of such considerations is reluctance of the authorities to attempt to create full employment through stimulative policies.

Inflation and growth

What emerges from these theories is a chain of causation that describes the way in which, in the period since World War II, inflation and growth have become causally connected through the responses of governments to actual and anticipated inflationary pressures. Inflation and the fear of inflation lead to slow growth and high unemployment because the inability of governments to bring inflation under control at full employment by other means—*e.g.*, an income policy—constrains governments to implement restrictive policies to combat or forestall inflationary pressures. Such responses lead, as they did in the early 1970s, not only to high rates of unemployment of capital and labour but also to low rates of investment and productivity growth. Stagnation is the result, and such a scenario is a likely prospect for capitalism in the future.

Foreign trade. Little has been said about foreign trade. Yet growth in most economies is very much dependent upon imports and the ability to export in order to pay for imports. The fact that some economies recovered relatively quickly from World War II and grew much more rapidly in the postwar period than others has stimulated a great deal of comparative analysis in growth theory. The exceptionally high growth rates in Japan and Germany compared to the general sluggishness of the British economy are related to foreign trade. Economists have pointed to the periodic balance of payments crises experienced by Britain and the lack of such crises in Germany. During a boom, as incomes rise the demand for imports will rise also as a natural feature of prosperity. But if exports do not also rise at the same time, the authorities may be forced to take fiscal or monetary countermeasures and slow down the economy in an effort to bring imports and exports back into balance. Or exports may fail to grow sufficiently because labour costs are rising very rapidly and pushing up prices of exports faster than in competing countries.

A policy of encouraging growth has the effect of keeping the demand for imports high and making labour markets tight, thereby tending to push up money wage rates. At the same time, such a policy also tends to encourage innovations and investment projects that are very productive, particularly if the demand pressures are sustained. A "stop" policy naturally has just the opposite effects, both good and bad from the point of view of a country's balance of payments. The question is which policy will in the long run result in less rapidly rising costs and prices. Many writers have argued that if demand pressures are maintained the response or adjustment of productivity and therefore of supply to these pressures will be such that the country will soon find itself in a more competitive position. Running an economy "flat out," however, is likely to cause a short-run balance of payments crisis and lead to devaluation of currency.

Mathematical growth theories. In addition to the theories discussed above, a large body of literature has developed involving abstract mathematical models. Because this field of analysis is so technical, only a general picture

of the kinds of problems and questions discussed can be given. First, a set of equations is drawn up describing what the model builder feels are the important relations between economic variables such as output, capital, investment, and consumption. These equations must relate economic variables to one another at different points in time: for example, output last year determines consumption this year, which in turn helps to determine output this year and therefore consumption and output next year. It is possible to work out the movements of the variables over as long a period as desired. At the centre of much of this analysis is the concept of a steady-state rate of growth: one in which all the economic variables contained in the set of equations grow at the same constant rate equal to the growth of the labour force.

Optimal growth models

A related class of studies attempts to take account of the welfare of workers and consumers in the maximization of growth. These "optimal growth" models seek to maximize consumer satisfaction over time. In a model such as this the solution will not be the highest possible growth rate but one that will maximize the welfare of consumers. The importance of such models for planners would seem to depend on the realism of their assumptions as to consumer desires and technology.

Model building and theorizing about growth has proceeded on various levels of abstraction. Some of the work is of little practical value, in the sense that its explanatory value is negligible. Such studies, however, may stimulate other work that is helpful in an understanding of the growth process. Some models, while realistic, are not applicable to all economies. Thus, a model that neglects international trade is of little use to a European economist trying to understand the more basic causes of differences in growth rates between countries. (J.L.C.)

Economic development

Economic development first became a major concern after World War II. As the era of European colonialism ended, many former colonies and other countries with low living standards came to be termed underdeveloped countries, to contrast their economies with those of the developed countries, which were understood to be Canada, the United States, those of western Europe, most eastern European countries, the then Soviet Union, Japan, South Africa, Australia, and New Zealand. As living standards in most poor countries began to rise in subsequent decades, they were renamed the developing countries.

There is no universally accepted definition of what a developing country is; neither is there one of what constitutes the process of economic development. Developing countries are usually categorized by a per capita income criterion, and economic development is usually thought to occur as per capita incomes rise. A country's per capita income (which is almost synonymous with per capita output) is the best available measure of the value of the goods and services available, per person, to the society per year. Although there are a number of problems of measurement of both the level of per capita income and its rate of growth, these two indicators are the best available to provide estimates of the level of economic well-being within a country and of its economic growth.

Difficulties of measurement

It is well to consider some of the statistical and conceptual difficulties of using the conventional criterion of underdevelopment before analyzing the causes of underdevelopment. The statistical difficulties are well known. To begin with, there are the awkward borderline cases. Even if analysis is confined to the underdeveloped and developing countries in Asia, Africa, and Latin America, there are rich oil countries that have per capita incomes well above the rest but that are otherwise underdeveloped in their general economic characteristics. Second, there are a number of technical difficulties that make the per capita incomes of many underdeveloped countries (expressed in terms of an international currency, such as the U.S. dollar) a very crude measure of their per capita real income. These difficulties include the defectiveness of the basic national income and population statistics, the inappropriateness of the official exchange rates at which the national incomes in terms of the respective domestic currencies are converted into the common denominator of the U.S. dollar, and the problems of estimating the value of the noncash components of real incomes in the underdeveloped countries. Finally, there are conceptual problems in interpreting the meaning of the international differences in the per capita income levels.

Per capita income comparisons

Although the difficulties with income measures are well established, measures of per capita income correlate reasonably well with other measures of economic well-being, such as life expectancy, infant mortality rates, and literacy rates. Other indicators, such as nutritional status and the per capita availability of hospital beds, physicians, and teachers, are also closely related to per capita income levels. While a difference of, say, 10 percent in per capita incomes between two countries would not be regarded as necessarily indicative of a difference in living standards between them, actual observed differences are of a much larger magnitude. India's per capita income, for example, was estimated at $270 in 1985. In contrast, Brazil's was estimated to be $1,640, and Italy's was $6,520. While economists have cited a number of reasons why the implication that Italy's living standard was 24 times greater than India's might be biased upward, no one would doubt that the Italian living standard was significantly higher than that of Brazil, which in turn was higher than India's by a wide margin.

The interpretation of a low per capita income level as an index of poverty in a material sense may be accepted with two qualifications. First, the level of material living depends not on per capita income as such but on per capita consumption. The two may differ considerably when a large proportion of the national income is diverted from consumption to other purposes; for example, through a policy of forced saving. Second, the poverty of a country is more faithfully reflected by the representative standard of living of the great mass of its people. This may be well below the simple arithmetic average of per capita income or consumption when national income is very unequally distributed and there is a wide gap in the standard of living between the rich and the poor.

The usual definition of a developing country is that adopted by the World Bank: "low-income developing countries" in 1985 were defined as those with per capita incomes below $400; "middle-income developing countries" were defined as those with per capita incomes between $400 and $4,000. To be sure, countries with the same per capita income may not otherwise resemble one another: some countries may derive much of their incomes from capital-intensive enterprises, such as the extraction of oil, whereas other countries with similar per capita incomes may have more numerous and more productive uses of their labour force to compensate for the absence of wealth in resources. Kuwait, for example, was estimated to have a per capita income of $14,480 in 1985, but 50 percent of that income originated from oil. In most regards, Kuwait's economic and social indicators fell well below what other countries with similar per capita incomes had achieved. Centrally planned economies are also generally regarded as a separate class, although China and North Korea are universally considered developing countries. A major difficulty is that prices serve less as indicators of relative scarcity in centrally planned economies and hence are less reliable as indicators of the per capita availability of goods and services than in market-oriented economies.

Estimates of percentage increases in real per capita income are subject to a somewhat smaller margin of error than are estimates of income levels. While year-to-year changes in per capita income are heavily influenced by such factors as weather (which affects agricultural output, a large component of income in most developing countries), a country's terms of trade, and other factors, growth rates of per capita income over periods of a decade or more are strongly indicative of the rate at which average economic well-being has increased in a country.

ECONOMIC DEVELOPMENT AS AN OBJECTIVE OF POLICY

Motives for development. The field of development economics is concerned with the causes of underdevelopment

and with policies that may accelerate the rate of growth of per capita income. While these two concerns are related to each other, it is possible to devise policies that are likely to accelerate growth (through, for example, an analysis of the experiences of other developing countries) without fully understanding the causes of underdevelopment.

Studies of both the causes of underdevelopment and of policies and actions that may accelerate development are undertaken for a variety of reasons. There are those who are concerned with the developing countries on humanitarian grounds; that is, with the problem of helping the people of these countries to attain certain minimum material standards of living in terms of such factors as food, clothing, shelter, and nutrition. For them, low per capita income is the measure of the problem of poverty in a material sense. The aim of economic development is to improve the material standards of living by raising the absolute level of per capita incomes. Raising per capita incomes is also a stated objective of policy of the governments of all developing countries. For policymakers and economists attempting to achieve their governments' objectives, therefore, an understanding of economic development, especially in its policy dimensions, is important. Finally, there are those who are concerned with economic development either because they believe it is what people in developing countries want or because they believe that political stability can be assured only with satisfactory rates of economic growth. These motives are not mutually exclusive. Since World War II many industrial countries have extended foreign aid to developing countries for a combination of humanitarian and political reasons.

Growth for stability

Those who are concerned with political stability tend to see the low per capita incomes of the developing countries in relative terms; that is, in relation to the high per capita incomes of the developed countries. For them, even if a developing country is able to improve its material standards of living through a rise in the level of its per capita income, it may still be faced with the more intractable subjective problem of the discontent created by the widening gap in the relative levels between itself and the richer countries. (This effect arises simply from the operation of the arithmetic of growth on the large initial gap between the income levels of the developed and the underdeveloped countries. As an example, an underdeveloped country with a per capita income of $100 and a developed country with a per capita income of $1,000 may be considered. The initial gap in their incomes is $900. Let the incomes in both countries grow at 5 percent. After one year, the income of the underdeveloped country is $105, and the income of the developed country is $1,050. The gap has widened to $945. The income of the underdeveloped country would have to grow by 50 percent to maintain the same absolute gap of $900.) Although there was once in development economics a debate as to whether raising living standards or reducing the relative gap in living standards was the true desideratum of policy, experience during the 1960–80 period convinced most observers that developing countries could, with appropriate policies, achieve sufficiently high rates of growth both to raise their living standards fairly rapidly and to begin closing the gap. (H.My./A.O.K.)

Compound growth of income gap

The impact of discontent. Although concern over the question of a subjective sense of discontent among the underdeveloped and developing countries has waxed and waned, it has never wholly disappeared. The underdeveloped countries' sense of dissatisfaction and grievance arises not only from measurable differences in national incomes but also from the less easily measurable factors, such as their reaction against the colonial past and their complex drives to raise their national prestige and achieve equality in the broadest sense with the developed countries. Thus, it is not uncommon to find their governments using a considerable proportion of their resources in prestige projects, ranging from steel mills, hydroelectric dams, universities, and defense expenditure to international athletics. These symbols of modernization may contribute a nationally shared satisfaction and pride but may or may not contribute to an increase in the measurable national income. Second, it is possible to argue that in many cases the internal gap in incomes within individual underdeveloped countries may be a more potent source of the subjective level of discontent than the international gap in income. Faster economic growth may help to reduce the internal economic disparities in a less painful way, but it must be remembered that faster economic growth also tends to introduce greater disruption and the need for making bigger readjustments in previous ways of life and may thus increase the subjective sense of frustration and discontent. Finally, it is difficult to establish that the subjective problem of discontent will bear a simple and direct relationship to the size of the international gap in incomes. Some of the apparently most discontented countries are to be found in Latin America, where the per capita incomes are generally higher than in Asia and Africa. A skeptic can turn the whole approach to a reductio ad absurdum by pointing out that even the developed countries with their high and rising levels of per capita income have not been able to solve the subjective problem of discontent and frustration among various sections of their population.

Two conclusions may be drawn from the above points. First, the subjective problem of discontent in the underdeveloped countries is a genuine and important problem in international relations. But economic policy acting on measurable economic magnitudes can play only a small part in the solution of what essentially is a problem in international politics. Second, for the narrower purpose of economic policy there is no choice but to fall back on the interpretation of the low per capita incomes of the underdeveloped countries as an index of their poverty in a material sense. This can be defended by explicitly adopting the humanitarian value judgment that the underdeveloped countries ought to give priority to improving the material standards of living of the mass of their people. But, even if this value judgment is not accepted, the conventional measure of economic development in terms of a rise in per capita income still retains its usefulness. The governments of the underdeveloped countries may wish to pursue other, nonmaterial goals, but they could make clearer decisions if they knew the economic cost of their decisions. The most significant measure of this economic cost can be expressed in terms of the foregone opportunity to raise the level of per capita income. (H.My.)

Toward a workable criterion

A SURVEY OF DEVELOPMENT THEORIES

The hypothesis of underdevelopment. If the underdeveloped countries are merely low-income countries, why call them underdeveloped? The use of the term underdeveloped in fact rests on a general hypothesis on which the whole subject matter of development economics is based. According to this hypothesis, the existing differences in the per capita income levels between the developed and the underdeveloped countries cannot be accounted for purely in terms of differences in natural conditions beyond the control of man and society. That is to say, the underdeveloped countries are underdeveloped because, in some way or another, they have not yet succeeded in making full use of their potential for economic growth. This potential may arise from the underdevelopment of their natural resources, or their human resources, or from the "technological gap." More generally, it may arise from the underdevelopment of economic organization and institutions, including the network of the market system and the administrative machinery of the government. The general presumption is that the development of this organizational framework would enable an underdeveloped country to make a fuller use not only of its domestic resources but also of its external economic opportunities, in the form of international trade, foreign investment, and technological and organizational innovations.

Development thought after World War II. After World War II a number of developing countries attained independence from their former colonial rulers. One of the common claims made by leaders of independence movements was that colonialism had been responsible for perpetuating low living standards in the colonies. Thus economic development after independence became an objective of policy not only because of the humanitarian desire to raise living standards but also because political promises had been made, and failure to make progress

Growth as a political desideratum

toward development would, it was feared, be interpreted as a failure of the independence movement. Developing countries in Latin America and elsewhere that had not been, or recently been, colonies took up the analogous belief that economic domination by the industrial countries had thwarted their development, and they, too, joined the quest for rapid growth.

At that early period, theorizing about development, and about policies to attain development, accepted the assumption that the policies of the industrial countries were to blame for the poverty of the developing countries. Memories of the Great Depression, when developing countries' terms of trade had deteriorated markedly, producing sharp reductions in per capita incomes, haunted many policymakers. Finally, even in the developed countries, the Keynesian legacy attached great importance to investment.

In this milieu, it was thought that a "shortage of capital" was the cause of underdevelopment. It followed that policy should aim at an accelerated rate of investment. Since most countries with low per capita incomes were also heavily agricultural (and imported most of the manufactured goods consumed domestically), it was thought that accelerated investment in industrialization and the development of manufacturing industries to supplant imports through "import substitution" was the path to development. Moreover, there was a fundamental distrust of markets, and a major role was therefore assigned to government in allocating investments. Distrust of markets extended especially to the international economy.

Experience with development changed perceptions of the process and of the policies affecting it in important ways. Nonetheless, there are significant elements of truth in some of the earlier ideas, and it is important to understand the thinking underlying them. (H.My./A.O.K.)

Growth economics and development economics. Development economics may be contrasted with another branch of study, called growth economics, which is concerned with the study of the long-run, or steady-state, equilibrium growth paths of the economically developed countries, which have long overcome the problem of initiating development.

Growth theory assumes the existence of a fully developed modern capitalist economy with a sufficient supply of entrepreneurs responding to a well-articulated system of economic incentives to drive the growth mechanism. Typically, it concentrates on macroeconomic relations, particularly the ratio of savings to total output and the aggregate capital–output ratio (that is, the number of units of additional capital required to produce an additional unit of output). Mathematically, this can be expressed (the Harrod–Domar growth equation) as follows: the growth in total output (g) will be equal to the savings ratio (s) divided by the capital–output ratio (k); *i.e.*, $g = \frac{s}{k}$. Thus, suppose that 12 percent of total output is saved annually and that three units of capital are required to produce an additional unit of output: then the rate of growth in output is $\frac{12}{3}\% = 4\%$ per annum. This result is obtained from the basic assumption that whatever is saved will be automatically invested and converted into an increase in output on the basis of a given capital–output ratio. Since a given proportion of this increase in output will be saved and invested on the same basis, a continuous process of growth is maintained.

Misapplication of growth theory

Growth theory, particularly the Harrod–Domar growth equation, has been frequently applied or misapplied to the economic planning of a developing country. The planner starts from a desired target rate of growth of perhaps 4 percent. Assuming a fixed overall capital–output ratio of, say, 3, it is then asserted that the developing country will be able to achieve this target rate of growth if it can increase its savings to 3×4 percent $= 12$ percent of its total output. The weakness of this type of exercise arises from the assumption of a fixed overall capital–output ratio, which assumes away all the vital problems affecting the developing country's capacity to absorb capital and invest its saving in a productive manner. These problems include the central problem of the efficient allocation of available savings among alternative investment opportunities and the associated organizational and institutional problems of encouraging the growth of a sufficient supply of entrepreneurs; the provision of appropriate economic incentives through a market system that correctly reflects the relative scarcities of products and factors of production; and the building up of an organizational framework that can effectively implement investment decisions in both the private and the public sectors. Such problems, which generally affect the developing country's absorptive capacity for capital and a number of other inputs, constitute the core of development economics. Development economics is needed precisely because the assumptions of growth economics, based as they are on the existence of a fully developed and well-functioning modern capitalist economy, do not apply.

The developing and underdeveloped countries are a very mixed collection of countries. They differ widely in area, population density, and natural resources. They are also at different stages in the development of market and financial institutions and of an effective administrative framework. These differences are sufficient to warn against wide-sweeping generalizations about the causes of underdevelopment and all-embracing theoretical models of economic development. But when development economics first came into prominence in the 1950s, there were powerful intellectual and political forces propelling the subject toward such general theoretical models of development and underdevelopment. First, many writers who popularized the subject were frankly motivated by a desire to persuade the developed countries to give more economic aid to the underdeveloped countries, on grounds ranging from humanitarian considerations to considerations of cold-war strategy. Second, there was the reaction of the newly independent underdeveloped countries against their past "colonial economic pattern," which they identified with free trade and primary production for the export market. These countries were eager to accept general theories of economic development that provided a rationalization for their deep-seated desire for rapid industrialization. Third, there was a parallel reaction, at the academic level, against older economic theory, with its emphasis on the efficient allocation of scarce resources and a striving after new and "dynamic" approaches to economic development.

Reasons for the change in theoretical models

All of these forces combined to produce a crop of theoretical approaches that soon developed into a fairly fixed orthodoxy with its characteristic emphasis on "crash" programs of investment in both material and human capital, on domestic industrialization, and on government economic planning as the standard ingredients of development policy. These new theories have continued to have a considerable influence on the conventional wisdom in development economics, although in retrospect most of them have turned out to be partial theories. A broad survey of these theories, under three main heads, is given below. It is particularly relevant to the debate over whether the underdeveloped countries should seek economic development through domestic industrialization or through international trade. The limitations of these new theories—and how they led to a gradual revival of a more pragmatic approach to development problems, which falls back increasingly on the older economic theory of efficient allocation of resources—are subsequently traced.

The missing-component approach. First, there are the theories that regard the shortage of some strategic input (such as the supply of savings, foreign exchange, or technical skills) as the main cause of underdevelopment. Once this missing component was supplied—say, by external economic aid—it was believed that economic development would follow in a predictable manner based on fixed quantitative relationships between input and output. The overall capital–output ratio, mentioned above, is the most well-known of these fixed technical coefficients. But similar fixed coefficients have been assumed between the foreign-exchange requirements and total output and between the input of skilled manpower and output. (H.My.)

Shortage of savings. Given the broad relationship between capital accumulation and economic growth es-

tablished in growth theory, it was plausible for growth theorists and development economists to argue that the developing countries were held back mainly by a shortage in the supply of capital. These countries were then saving only 5–7 percent of their total product, and it was manifest (and it remains true) that satisfactory growth cannot be supported by so low a level of investment. It was therefore thought that raising the savings ratio to 10–12 percent was the central problem for developing countries. Early development policy therefore focused on raising resources for investment. Steps toward this end were highly successful in most developing countries, and savings ratios rose to the 15–25 percent range. However, growth rates failed even to approximate the savings rates, and theorists were forced to search for other explanations of differences in growth rates.

Aid and growth

It has become increasingly clear that there can be much wastage of capital resources in the developing countries for various reasons, such as wrong choice of investment projects, inefficient implementation and management of these projects, and inappropriate pricing and costing of output. These faults are particularly noticeable in public-sector investment projects and are one of the reasons why the Pearson Commission Report of the International Bank for Reconstruction and Development (1969) found that "the correlation between the amounts of aid received in the past decades and the growth performance is very weak." But even in the private sector there may be a considerable distortion in the direction of investment induced by policies designed to encourage development. Thus, in most underdeveloped countries, a considerable part of private expansion investment, both foreign and domestic, has been diverted into the expansion of the manufacturing sector, catering to the domestic market through various inducements, including tariff protection, tax holidays, cheap loans, and generous foreign-exchange allocations granting the opportunity to import capital goods cheaply at overvalued exchange rates. As a consequence, there developed a very considerable amount of excess capacity in the manufacturing sector of the underdeveloped countries pursuing such policies.

Foreign-exchange shortage. In the 1950s most developing countries were primary commodity exporters, relying on crops and minerals for the bulk of their foreign-exchange earnings through exports, and importing a large number of manufactured goods. The experience of colonialism, and the distrust of the international economy that it engendered, led policymakers in most developing countries to adopt a policy of import substitution. This policy was intended to promote industrialization by protecting domestic producers from the competition of imports. Protection, in the form of high tariffs or the restriction of imports through quotas, was applied indiscriminately, often to inherently high-cost industries that had no hope of ever becoming internationally competitive. Also, after the early stages of import substitution, protected new industries tended to be very intensive in the use of capital and especially of imported capital goods.

The import-substitution approach defined "industrialization" rather narrowly as the expansion of the modern manufacturing sector based on capital-intensive technology. Capital was therefore identified with durable capital equipment in the form of complex machinery and other inputs that the underdeveloped countries were not able to produce domestically. Thus, foreign-exchange requirements were calculated on the basis of the fixed technical input-output coefficients of the manufacturing sector.

With high levels of protection for domestic industry, and with exchange rates that were often maintained at unrealistic levels (usually in an effort to make imported capital goods "cheap"), the experience of most developing countries was that export earnings grew relatively slowly. The simultaneously sharp increase in demand for imported capital goods (and for raw materials and replacement parts as well) resulted in unexpectedly large increases in imports. Most developing countries found themselves with critical foreign-exchange shortages and were forced to reduce imports in order to cut their current-account deficits to manageable proportions.

The cutbacks in imports usually resulted in reduced growth rates, if not recessions. This result led to the view that economic stagnation was caused primarily by a shortage of foreign exchange with which to buy essential industrial inputs. But over the longer term the growth rates of countries that continued to protect their domestic industries heavily not only stagnated but declined sharply. Contrasting the experience of countries that persisted in policies of import substitution with those that followed alternative policies (see below) subsequently demonstrated that foreign-exchange shortage was a barrier to growth only within the context of the protectionist policies adopted and was not inherently a barrier to the development process itself. (H.My./A.O.K.)

Education and human capital in development. As it became apparent that the physical accumulation of capital was not by itself the key to development, many analysts turned to a lack of education and skills among the population as being a crucial factor in underdevelopment. If education and skill are defined as everything that is required to raise the productivity of the people in the developing countries by improving their skills, enterprise, initiative, adaptability, and attitudes, this proposition is true but is an empty tautology. However, the need for skills and training was first formulated in terms of specific skills and educational qualifications that could be supplied by crash programs in formal education. The usual method of manpower planning thus started from a target rate of expansion in output and tried to estimate the numbers of various types of skilled personnel that would be required to sustain this target rate of economic growth on the basis of an assumed fixed relationship between inputs of skill and national output.

This approach was plausible enough in many developing countries immediately after their political independence, when there were obvious gaps in various branches of the administrative and technical services. But most countries passed through this phase rather quickly. In the meantime, as the result of programs in education expansion, their schools and colleges began producing large numbers of fresh graduates at much faster rates than their general rate of economic growth could supply suitable new jobs for. This created a growing problem of educated unemployment. An important factor behind the rapid educational expansion was the expectation that after graduation students would be able to obtain well-paying white-collar jobs at salary levels many times the prevailing per capita income of their countries. Thus, the underdeveloped countries' inability to create jobs to absorb their growing armies of graduates created an explosive element in what came to be called the revolution of expectations.

Educated unemployment

It is possible to see a close parallelism between the narrow concept of industrialization as the expansion of the manufacturing sector and the narrow concept of education as the academic and technical qualifications that can be supplied by the expansion of the formal educational system. If a broader concept of education, relevant for economic development, is needed, it is necessary to seek it in the pervasive educational influence of the economic environment as a whole on the learning process of the people of the underdeveloped countries. This is a complex process that depends on, among other less easily analyzable things, the system of economic incentives and signals that can mold the economic behaviour of the people of the underdeveloped countries and affect their ability to make rational economic decisions and their willingness to introduce or adapt to economic changes. Unfortunately, the economic environment in many underdeveloped countries is dominated by a network of government controls that tend not to be conducive to such ends.

Surplus resources and disguised unemployment. Two theories emphasized the existence of surplus resources in developing countries as the central challenge for economic policy. The first concentrated on the countries with relatively abundant natural resources and low population densities and argued that a considerable amount of both surplus land and surplus labour might still exist in these countries because of inadequate marketing facilities and lack of transport and communications. Economic devel-

opment was pictured as a process whereby these underutilized resources of the subsistence sector would be drawn into cash production for the export market. International trade was regarded as the chief market outlet, or vent, for the surplus resources. The second theory was concerned with the thickly populated countries and the possibility of using their surplus labour as the chief means of promoting economic development. According to this theory, because of heavy population pressure on land, the marginal product of labour (that is, the extra output derived from the employment of an extra unit of labour) was reduced to zero or to a very low level. But the people in the subsistence sector were able to enjoy a certain customary minimum level of real income because the extended-family system of the rural society shared the total output of the family farm among its members. A considerable proportion of labour in the traditional agricultural sector was thus thought to contribute little or nothing to total output and to really be in a state of disguised unemployment. By this theory, the labour might be drawn into other uses without any cost to society.

The concept of disguised unemployment

It is necessary to clear up a number of preliminary points about the concept of disguised unemployment before considering its applications. First, it is highly questionable whether the marginal product of labour is actually zero even in densely populated countries such as India or Pakistan. Even in these countries, with existing agricultural methods, all available labour is needed in the peak seasons, such as harvest. The most important part of disguised unemployment is thus what may be better described as seasonal unemployment during the off-seasons. The magnitude of this seasonal unemployment, however, depends not so much on the population density on land as on the number of crops cultivated on the same piece of land through the year. There is thus little seasonal unemployment in countries such as Taiwan or South Korea, which have much higher population densities than India, because improved irrigation facilities enable them to grow a succession of crops on the same land throughout the year. But there may be considerable seasonal unemployment even in sparsely populated countries growing only one crop a year.

Seasonal unemployment

The main weakness in the proposal to use disguised unemployment for the construction of major social-overhead-capital projects arises from an inadequate consideration of the problem of providing the necessary subsistence fund to maintain the workers during what may be a considerably long waiting period before these projects yield consumable output. This may be managed somehow for small-scale local-community projects when the workers are maintained in situ by their relatives. But when it is proposed to move a large number of surplus workers away from their home villages for major construction projects taking a considerable time to complete, the problem of raising a sufficient subsistence fund to maintain the labour becomes formidable. The only practicable way of raising such a subsistence fund is to encourage voluntary saving and the expansion of a marketable surplus of food that can be purchased with the savings to maintain the workers. The mere existence of disguised unemployment does not in any way ease this problem. (H.My.)

Role of governments and markets. In earlier thinking about development, it was assumed that the market mechanisms of developed economies were so unreliable in developing economies that governments had to assume central responsibility for economic activity. This was to be done through economic planning for the entire economy (see below *Planning in developing countries*), which in turn would be implemented by active government participation in the economy and pervasive controls over all private-sector economic activity. Government participation took many forms: Public-sector enterprises were established to manufacture many commodities, including steel, machine tools, fertilizers, heavy chemicals, and even textiles and clothing; government marketing boards assumed monopoly power over the purchase and sale of many agricultural commodities; and government agencies became the sole importers of a variety of goods, and they often became exporters as well. Controls over private-sector activity were even more extensive: Price controls were established for many commodities; import licensing procedures eliminated the importing of commodities not given priority in official plans; investment licenses were required before factories could be expanded; capacity licenses regulated maximum permissible outputs; and comprehensive regulations governed the conditions of employment of workers.

Distrust of market mechanisms

The consequence, frequently, was that indigenous entrepreneurs often found it more financially rewarding to devote their energies and ingenuity to the task of procuring the necessary government import licenses and other permits and exploiting the loopholes in government regulations than to the problem of raising the efficiency and productivity of resources. For public-sector enterprises, political pressures often resulted in the employment of many more persons than could be productively used and in other practices conducive to extremely high-cost and inefficient operations. The consequent fiscal burden diverted resources that might otherwise have been used for investment, while the inefficient use of resources dampened growth rates.

Related to the belief in market failure and in the necessity for government intervention was the view that the efficiency of the price mechanism in developing countries was very small. This was reflected in the view of foreign-exchange shortage, already discussed, in which it was thought that there are fixed relationships between imported capital and domestic expansion. It was also reflected in the view that farmers are relatively insensitive to relative prices and in the belief that there are few entrepreneurs in developing countries.

LESSONS FROM DEVELOPMENT EXPERIENCE

By the end of the 1950s the experience gained from efforts to promote economic development showed great differences among developing countries. Some had broken away relatively quickly from the import-substitution, government-control and -ownership pattern that had been the early development wisdom. Others persisted with the same policies for several decades. A great deal was learned from the experiences of different developing countries.

The importance of agriculture. Despite early emphasis on industrialization through import substitution, a first major lesson of postwar experience was that there is a close connection between the rate of growth in the output of the agricultural sector and the general rate of economic development. The high rates of economic growth are associated with rapid expansion of agricultural output and low rates of economic growth with the slow growth of agriculture. This is (in hindsight, at least) to be expected, since agriculture forms a large part of the total domestic product and of the exports of the developing countries. What is more interesting is that the expansion of agricultural output was by no means confined to those countries with an abundant supply of unused land to be brought under cultivation. Taiwan and South Korea, with some of the highest population densities in the world, were able to expand their agricultural output rapidly by a vigorous pursuit of appropriate policies. These included the provision of adequate irrigation facilities, enabling a succession of crops to be grown on the same piece of land throughout the year; the use of high-yielding seeds and fertilizers, which raised the yields per acre in a dramatic fashion; provision of adequate incentives for producers by setting producer prices at reasonable levels; and improvements in credit and marketing facilities and a general improvement in the economic organization of the agricultural sector. Agricultural development is important because it raises the incomes of the mass of the people in the countryside; in addition, it increases the size of the domestic market for the manufacturing sector and reduces internal economic disparities between the urban centres and the rural districts.

The role of exports. A second conclusion to be drawn from experience is the close connection between export expansion and economic development. The high-growth countries were characterized by rapid expansion in exports. Here again it is important to note that export ex-

pansion was not confined to those countries fortunate in their natural resources, such as the oil-exporting countries. Some of the developing countries were able to expand their exports in spite of limitations in natural resources by initiating economic policies that shifted resources from inefficient domestic manufacturing industries to export production. Nor was export expansion from the developing countries confined to primary products. There was very rapid expansion of exports of labour-intensive manufactured goods. This phenomenon occurred not only in the extremely rapidly growing, newly industrialized countries (NICs)—Singapore, Hong Kong, South Korea, and Taiwan—but also from other developing countries including Brazil, Argentina, and Turkey. Countries that adopted export-oriented development strategies (of which the most notable were the NICs) experienced extremely high rates of growth that were regarded as unattainable in the 1950s and 1960s. They were also able to maintain their growth momentum during periods of worldwide recession better than were the countries that maintained their import substitution policies.

The newly industrialized countries (NICs)

Analysts have pointed to a number of reasons why the export-oriented growth strategy seems to deliver more rapid economic development than the import substitution strategy. First, a developing country able to specialize in producing labour-intensive commodities uses its comparative advantage in the international market and is also better able to use its most abundant resource—unskilled labour. The experience of export-oriented countries has been that there is little or no disguised unemployment once labour-market regulations are dismantled and incentives are created for individual firms to sell in the export market. Second, most developing countries have such small domestic markets that efforts to grow by starting industries that rely on domestic demand result in uneconomically small, inefficient enterprises. Moreover, those enterprises will typically be protected from international competition and the incentives it provides for efficient production techniques. Third, an export-oriented strategy is inconsistent with the impulse to impose detailed economic controls; the absence of such controls, and their replacement by incentives, provides a great stimulus to increases in output and to the efficiency with which resources are employed. The increasing capacity of a developing country's entrepreneurs to adapt their resources and internal economic organization to the pressures of world-market demand and international competition is a very important connecting link between export expansion and economic development. It is important in this connection to stress the educative effect of freer international trade in creating an environment conducive to the acceptance of new ideas, new wants, and new techniques of production and methods of organization from abroad.

The negative effect of controls. Another major lesson that was learned is that poor people are, if anything, more responsive to incentives than rich people. Nominal exchange rates that are pegged without regard to domestic inflation have strong negative effects on incentives to export; producer prices for agricultural goods that are set as a small fraction of their world market price constitute a significant disincentive to agricultural production; and controls on prices and investment serve as significant deterrents to economic activity. Indeed, in most environments, controls lead to "rent-seeking" behaviour, in which resources are diverted from productive activity and instead are used to try to win import licenses, or to get the necessary bureaucratic permissions. In addition, in many countries, "parallel," or black, markets emerged, which diverted resources from activities in the official sector. In some countries, legal exports diminished sharply as smuggling and underinvoicing intensified in response to increasing discrepancies between the official exchange rate and the black-market rate.

Incentives and disincentives

The importance of appropriate incentives. As a corollary to the lesson that controls may strongly divert economic activity from an efficient allocation of resources, it became increasingly evident that inappropriate incentives can adversely affect economic behaviour. The response of agricultural supply to increases in producer prices is considerably stronger than was earlier believed. Likewise, individuals respond to incentives with respect to their education and training. Thus, much of the overinvestment in education referred to earlier came to be seen as the result of artificially inflated wages for university graduates in the public sector and of the fact that university education was virtually free to students in many developing countries. As a consequence, students perceived an incentive to obtain university degrees, even when there was a chance that they would remain unemployed for an extended period of time. When they did eventually find employment, the high wage would compensate for their earlier period of unemployment. Privately, such behaviour makes good sense in response to existing incentives; socially, however, it represents a waste of valuable and scarce resources.

The role of the international economy. In the modern view of development, an open, expanding international economy is the greatest support that the developed countries can provide for developing countries. Foreign aid can be extremely helpful in situations in which policies are conducive to development, but development will in any event be accelerated if the international economy is experiencing healthy growth. Removal of the trade barriers that developed countries have erected against developing countries is at least as important as economic aid. Trade barriers are many. They include restrictions on temperate-zone agricultural products and sugar; restrictions on the simpler labour-intensive manufactured goods (which often can be produced more cheaply in developing countries) including especially the Multifibre Arrangement under which imports of textiles and clothing into developed countries are greatly restricted; and tariff escalation, or higher rates of duties on processed products as compared with raw materials, which discourages the growth of processing industries in the developing countries. The removal of these trade barriers can help those developing countries that have already shown their capacity to take advantage of the available external economic opportunities to grow even more satisfactorily and can also provide additional incentives for other developing countries to alter their economic policies.

The Multifibre Arrangement

Population growth. Still another lesson is the desirability of slowing down the rapid population growth that characterizes most developing countries. Their average rate of population growth is about 2.2 percent per year, but there are some countries where population growth is 3 percent or more. If the aim of economic development is to raise the level of per capita incomes, it is obvious that this can be achieved both by increasing the rate of growth of total output and by reducing the rate of growth of population. Development economists of the 1950s tended to neglect population-control policies. They were partly seduced by theories of dramatically raising total output through crash investment programs and partly by the belief that population growth could be controlled only slowly, through gradual changes in social attitudes and values. But it is now recognized that some births in developing countries are unwanted. Great technical advances in methods of birth control about the same time made possible mass dissemination at very low cost. Countries where these methods were made available experienced significant declines in birth rates, although significant changes in social attitudes and values are necessary before average family size declines enough to halt population growth. As soon as birth rates stop rising, the relative increase in population in the working-age groups and the higher income available to existing family members immediately start to release resources for increasing consumption and saving.

Development of domestic industry. The positive case for the expansion of the manufacturing sector may now be considered. It is based on the general assumption that the manufacturing sector will in due course become the leading sector, drawing in workers (in part, siphoning off a portion of the increase in the labour force that would otherwise tend to drive down labour productivity in agriculture) from the traditional agricultural sector and providing them with higher-productivity jobs than could be obtained in agriculture. Agricultural productivity would necessarily be rising simultaneously, as investments in that

sector permitted increasing output. Whereas it was earlier thought that this process would follow the historical experience of countries such as England and Japan, the lesson from the successful developing countries is that by providing incentives and infrastructural support to encourage exports, there are significant opportunities for expansion of manufacturing of labour-intensive commodities, opportunities that can promote rapid growth.

Thus, given the much greater size of the international economy, and the much lower transport and communications costs that confront contemporary developing countries as contrasted with conditions in the 19th century, the potential for rapid growth is much greater now. Countries such as South Korea and Taiwan have experienced in a decade proportionate increases in per capita incomes that it took England and Japan a century to achieve. Whether other developing countries can follow this lead depends on a number of factors, including their economic policies and the continued growth of the international economy. (H.My./A.O.K.)

The central problem of countries with low per capita output is that they have not as yet succeeded in making use of their potential economic opportunities. To do so, they must achieve an efficient allocation of the available resources and provide incentives for resource accumulation. But efficient allocation of resources is not merely a matter of the formal optimum conditions of economic theory. It requires the building up of an effective institutional and organizational framework to carry out the allocation of resources. In the private sector this requires the development of a well-articulated market system that embraces the markets for final products and the markets for factors of production. In the public sector the development of the organizational framework requires improvements in the administrative machinery of the government, especially in its fiscal machinery.

Long-range planning of resource allocation

In the setting of the developing countries, one is concerned not only with the once for all problem of efficient allocation of resources but also with improving the capacity of these countries to make a more effective use of their resources over a period of time. That is to say, one is concerned not only with the static problem of the efficient allocation of given resources with the given organizational framework but also with dynamic problems of improving the capability of this framework. From this point of view, there is no conflict, as some have maintained, between the static, or the short-run, considerations and the dynamic, or long-run, considerations. The two sets of requirements move in the same direction.

The problem of the efficient allocation of investable funds in the developing countries may be taken as an example. Static rules would require the developing countries to have higher rates of interest to reflect their greater capital scarcity. But many developing countries, under the influence of dynamic theories of economic development, have used a variety of direct and indirect controls to divert large sums of capital to the manufacturing sector in the form of loans at interest rates well below the level required to equate the demand and supply of capital funds. This practice has resulted not only in a wasteful use of scarce capital resources but also in a retardation of the development of a domestic capital market. Instead of developing a unified capital market for the whole country, it aggravates the financial dualism characterized by low rates of interest in the modern sector and high rates in the traditional sector. The policy of keeping the official rate of interest below the equilibrium rate of interest also results in an excess demand for loans, leading to domestic inflation and pressure on the balance of payments and to a discouragement of the growth of domestic savings. Few private individuals are prepared to buy government securities when they frequently carry rates of interest below the rate of depreciation in the value of money. Through the pursuit of "cheap money" policies that contradict the real facts of capital scarcity, the governments of developing countries have failed to make use of the opportunity of building up a domestic capital market based on an expanding volume of transactions in government securities. (H.My.)

Developing countries and debt. After World War II it was thought that developing countries would require foreign aid in their early stages of development. This aid would supplement the capital created by domestic savings, permitting a higher rate of investment and thus stimulating growth. It was expected that their reliance on official sources of additional capital would continue until their economies had progressed enough to gain them access to private international capital markets.

Until the 1980s this pattern seemed to evolve as predicted. In the 1950s almost all capital flows to developing countries were from official sources, in the form of foreign aid from developed countries or of resources from the multilateral institutions, the World Bank and the International Monetary Fund. In the 1960s some of the export-oriented, rapidly growing countries began to rely on private international capital markets. Some, such as Singapore, attracted direct private foreign investment; others, such as South Korea, relied more on borrowing from commercial banks. In the 1970s many oil-importing developing countries were able to turn to borrowing from private sources when their economies were hit by the severe oil price increase of 1973.

The borrowing by rapidly growing countries was of the type earlier envisaged. Investment yielded a very high rate of return in these countries, so additional foreign resources could be attracted and productively used. However, some other countries borrowed in order to offset higher oil prices and in order to maintain an excess of expenditures over consumption, without developing the highly profitable investments with which to finance the debt-servicing obligations they incurred. Balance-of-payments crises and debt-servicing difficulties had been experienced by a few countries in most years since the 1950s, but with the second oil price increase and the worldwide recession of the early 1980s, developing countries increased their borrowing and total indebtedness sharply until commercial banks virtually ceased voluntary lending after Mexico experienced difficulty meeting its obligations in 1982. The result was that a large number of developing countries were unable to meet their debt obligations, as export earnings declined owing to the recession, interest rates were rising, and new money was not forthcoming.

The impact of oil prices

For many heavily indebted developing countries, the consequence was a prolonged period of slow growth or even declines in outputs and incomes. The lessons were several: The buoyant conditions of the 1970s were not likely to recur, and policies that had sustained satisfactory growth rates in those conditions were not likely to do so in the future; countries that had not yet moved away from import-substitution policies and direct governmental controls would need to undertake structural adjustments rather rapidly in order to resume their growth and to restore creditworthiness; and future private lending to developing countries would need to be somewhat more discriminating as to the economic prospects of recipient countries.

DEVELOPMENT IN A BROADER PERSPECTIVE

Modern economic development started in Great Britain, which in the 1780s accounted for a little over 1 percent of the total world population at that time. Since then, economic development has spread in widening circles to other parts of the world, spurred on by a series of technological innovations, particularly in the form of improvements in transport and communications. In the early decades of the 19th century the circle of the developed countries was limited to western Europe. By the late 19th century the circle had widened to include North America, Australia and New Zealand, and Japan. By the early 1970s about 34 percent of the total world population belonged to the developed countries, which among them had 87.5 percent of the total world GNP. What are the prospects of the still-to-develop countries of Asia, Latin America, and Africa joining this circle of economic development?

On the negative side there are a number of factors that add to their difficulties. First, the level of per capita product in the present-day developing countries is much lower than in the developed countries in their preindustrialization phase (with the exception of Japan). Second, the present-day developing countries have large popula-

tion bases and are handicapped by much faster rates of population growth. Third, they have generally a much weaker social and political framework to cope with the more explosive forces of discontent engendered by their reaction against their colonial past and by their internal economic disparities.

Factors favouring economic development

On the positive side, the present-day developing countries can draw upon a greater store of scientific and technical knowledge from the developed countries. The potential opportunities to exploit the "technological gap" are not confined to manufacturing. Modern science and technology can make immense contributions to agriculture, as illustrated by the Green Revolution created by the introduction of improved seeds and fertilizers in some Asian and Latin-American countries. Modern methods of birth control can make a decisive contribution in the race for raising per capita incomes. In addition, as the circle of the developed countries widens, they are bound to exert an increasing upward pull on the developing countries.

The economic growth of the developed countries has generally resulted in an expanding demand for the products and sometimes for direct labour services from the developing countries. But there are also the stronger localized pulls, such as the pull of the United States economy on Mexico and the pull of western Europe on the developing countries of southern Europe. The spectacular economic growth of Japan since World War II may also exert a similar pull on neighbouring countries in East Asia.

Countries such as South Korea, Taiwan, and Singapore are rapidly approaching developed-country status, and the circle is widening still farther. Rapid growth rates are being experienced by many countries in Southeast Asia. If one considers the successful developing countries of the 1950s and 1960s, it is evident that the rapid growth of the international economy was a very positive contributing factor in their success. Future widening of the circle will no doubt depend in large part on whether the growth of the international economy attains a satisfactory level.

In conclusion, the experience of the postwar years has provided many lessons that form a basis for optimism. A great deal has been learned about the types of economic policies that are conducive to rapid economic development. Rates of growth of per capita income experienced by the developing countries have been significantly higher than had been achieved by the first countries to develop. Attainable rates of growth of per capita income appear to be far above what formerly was thought feasible. The chief potential obstacles to successful development appear to be the spectre of disintegration of the international economy, should protectionist pressures be increasingly effective, and the inability or unwillingness of leaders in developing countries to adopt policies conducive to rapid economic growth. (H.My./A.O.K.)

Economic productivity

Productivity in economics is the ratio of what is produced to what is required to produce it. Usually this ratio is in the form of an average, expressing the total output of some category of goods divided by the total input of, say, labour or raw materials. In principle, any input can be used in the denominator of the productivity ratio. Thus, one can speak of the productivity of land, labour, capital, or subcategories of any of these factors of production. One may also speak of the productivity of a certain type of fuel or raw material or may combine inputs to determine the productivity of labour and capital together or of all factors combined. The latter type of ratio is called "total factor" or "multifactor" productivity, and changes in it over time reflect the net saving of inputs per unit of output and thus increases in productive efficiency. It is sometimes also called the residual, since it reflects that portion of the growth of output that is not explained by increases in measured inputs. The partial productivity ratios of output to single inputs reflect not only changing productive efficiency but also the substitution of one factor for another—*e.g.*, capital goods or energy for labour.

Labour is by far the most common of the factors used in measuring productivity. One reason for this is, of course, the relatively large share of labour costs in the value of most products. A second reason is that labour inputs are measured more easily than certain others, such as capital. This is especially true if by measurement one means simply counting heads and neglecting differences among workers in levels of skill and intensity of work. In addition, statistics of employment and labour-hours are often readily available, while information on other productive factors may be difficult to obtain. Although ratios of output to persons engaged in production or to labour-hours are referred to as labour productivity, the term does not imply that labour is solely responsible for changes in the ratio. Improvements in output per unit of labour may be due to increased quality and efficiency of the human factor but also to many other variables discussed later. There is special interest in labour productivity measures, however, since human beings are the end as well as a means of production.

The productivity of labour, land, and capital

The productivity of land, though it receives considerably less attention than the productivity of labour, has been of historical interest. In ancient and preindustrial times the products of the soil constituted the bulk of total output, and land productivity thus constituted the major ingredient in a people's standard of living. Soil of low productivity could, and over much of the Earth still does, mean poverty for a region's inhabitants. It is, however, no longer generally believed, as it was in past centuries, that a country's economic well-being is inevitably tied to the productive powers of the land, and the productive potential of the land itself has proved to be not fixed but greatly expandable through the use of modern agricultural methods. Moreover, industrialization, where it has taken place, has greatly reduced people's dependence on agriculture. These circumstances, together with expanding opportunities for trade, have enabled some countries to overcome in substantial degree the handicaps of a meagre agricultural endowment.

Attempts to measure the productivity of capital

The productivity of capital—plant, equipment, tools, and other physical aids—is a subject of long-standing interest to economists, though concern with its empirical aspects is of more recent origin. Improved statistical reporting and the availability of data in some industrially advanced countries, notably since World War II, have encouraged systematic efforts to measure the productivity of this factor. Compared with achievements in measuring labour productivity, however, the progress realized has been quite limited. There are considerable theoretical and practical difficulties to be overcome.

USES OF PRODUCTIVITY MEASUREMENT

Index of growth. A nation or an industry advances by using less to make more. Labour productivity is an especially sensitive indicator of this economizing process and is one of the major measures used to chart a nation's or an industry's economic advance. An overall rise in a nation's labour productivity signifies the potential availability of a larger quantity of goods and services per worker than before and, accordingly, a potential for higher real income per worker. Countries with high real wages are usually also those with high labour productivity, while those with low real wages are generally low in productivity. If, for the moment, other productive factors are neglected, one can see that the wage level will then be equal to the total national product divided by the number of workers; that is, it will be equal to the level of labour productivity.

The change in a nation's overall labour productivity during any given interval represents the sum of changes in the major economic sectors and industries. Some sectors and industries move ahead more rapidly than the overall average while others may gain more slowly or even decline. In the movement of a country from a level of low productivity and low income to one of high productivity and high income a strategic role is played by the industrial, rather than by the agricultural and other, sectors. In the late 18th and early 19th centuries the effect of the Industrial Revolution was felt first in the manufacture of woolen and cotton textiles, power generation, the metal trades, and machine-making industries. Along with the development of new processes came the development of

new products and services that formed the basis for new industries. An outstanding feature of these changes was an increased labour productivity that in turn laid the foundations for an enormous expansion of output. Technological change exerted its influence irregularly and unevenly and continues to do so.

In the compilation of overall averages this diversity is concealed because high rates in some industries offset low rates in others. Thus, the rate of increase of productivity for the economy as a whole varies within narrower limits than the spread of rates among individual industries would suggest. Aside from erratic short-term movements, the rate of growth of productivity may appear to be fairly stable over extended periods. A surge of labour-saving innovations would cause the overall average rate to move higher, while a technological lull would depress the average rate. History suggests that the surges tend to be associated with basic technological changes such as, for example, the steam engine, the gasoline engine, the electric motor, and the concept of the standardization of parts. Once introduced, such inventions or developments are used in many different industries. These surges tend also to be associated with such developments as, for instance, employment of the open-hearth furnace in steel manufacture or the introduction of the steam railroad.

Technological change

Productivity is valuable also as an indicator of comparative rates of change among industries and products. Growth in general can be better understood if the relative contributions of individual industries and the circumstances underlying productivity changes in each of these industries are understood.

Measure of efficiency. Productivity is also used to measure efficiency, as an aid in economic planning and forecasting, and as a means of assessing the uses to which resources are being put. As to the first of these, the efficiency of industrial operations, for instance, may be evaluated by the yardstick of output per worker or machine, and such a yardstick may also provide the basis for supplemental or premium payments for workers. When pay is based on piecework alone, labour productivity becomes the sole determinant. Productivity may also serve as a standard for grading and evaluating any group of workers performing common tasks, distinguishing the more from the less productive. And applied to equipment, productivity standards can indicate when a machine is performing poorly and is in need of service. In forecasting, productivity estimates are useful when it is necessary to be able to project the performance of the economy at some future date, given the probable size of the working force. A variant of this is common in planning for developing countries that want to increase their productivity; information about target levels of productivity, together with expectations as to the growth of the labour force and some understanding of the relation between capital per worker and output per worker, helps in estimating the amount of capital investment needed to reach the target. Again, estimates of the probable annual gain in labour productivity together with estimates of the probable annual increase in output allow one to estimate how many jobs will become available at some time in the future. Finally, productivity is a helpful analytical tool in studying the possible allocation of resources among different uses. The extent to which resources flow to various uses depends, among other things, on their productivity in each of those uses. Changes in productivity in the course of time alter the pattern of use and cause the quantities of resources required in particular uses to change. The resulting trends depend on several things. On the one hand, an increase in the productivity of, for instance, labour, since it means a decrease in labour requirements per unit of output, will tend to reduce the demand for labour. But it will also imply a cheapening of labour relative to the cost of other competing factors of production. Hence there will be a tendency to substitute labour for other factors. When labour cost represents a large fraction of total cost, a productivity increase will contribute toward a reduction in the price of the product, thereby expanding sales and with them the demand for labour. The net result will depend upon the sum total of all of these separate effects. It is by no means uncommon to find that the expansionary effects predominate, and many economists consider this to be the normal outcome. In any event, the productivity concept and data on productivity trends can contribute to an understanding of resource and output flows.

Wage and price analysis. Real average labour compensation has increased over the long run at about the same pace as labour productivity. The association of these two variables must be close so long as the labour share of total cost does not change much. If nominal average earnings were to increase more than labour productivity, labour cost per unit of output would rise and so would prices unless profit margins were reduced to compensate. In general, prices rise by less than wage rates and other input prices to the extent that total productivity rises. Productivity growth is thus an anti-inflationary factor, although inflation is basically a monetary phenomenon.

There is a significant negative correlation between relative industry changes in productivity and in prices—when productivity rises, price tends to fall. In the industrial sector of an economy in which there is a significant price elasticity of demand (*i.e.*, where price is relatively responsive to changes in demand), there is also a significant positive correlation between relative industry changes in productivity and in output—when productivity rises, output tends to rise as well. This is an interactive relationship, since the tendency of price to fall as productivity increases is reinforced by the tendency of economies of scale made possible by increased output to further enhance productivity.

Relation of prices and productivity

In dynamic economies the supply of capital has risen faster than the size of the labour force, and wage rates have risen faster than the price of capital. As a result there has been a marked tendency to substitute capital for labour in almost all industries. Yet there has been no long-term trend toward increased unemployment because real aggregate demand has tended to rise enough to absorb the growth of the labour force. Cyclical fluctuations in output and employment in capitalist countries are not the result of technological displacements of labour but rather reflect macroeconomic variables, such as growth of the money supply, that affect aggregate demand.

FACTORS THAT DETERMINE PRODUCTIVITY LEVELS

The level of productivity in a country, industry, or enterprise is determined by a number of factors. These include the available supplies of labour, land, raw materials, capital facilities, and mechanical aids of various kinds. Included also are the education and skills of the labour force; the level of technology; methods of organizing production; the energy and enterprise of managers and workers; and a range of social, psychological, and cultural factors that underlie and condition economic attitudes and behaviour.

These variables interact and mutually condition one another in determining productivity levels and their changes. Thus, in any country one expects the level of technology, the skills of the work force, the quantity of capital, and the capacity for rational economic organization to be positively correlated. A country with low productivity is likely to have deficiencies on all counts; a country with high productivity is likely to score high on all. To put it differently, the numerous productivity-determining factors behave as variables in a system of simultaneous equations, with all acting concurrently to shape the outcome. Within this system, there are no grounds for assigning causal priority to one or a few variables. All interact mutually to determine the outcome. Within certain problem frameworks, however, it may be entirely appropriate and indeed essential for explanatory purposes to emphasize certain variables over others.

Two broad problem frameworks may be distinguished, both of them of concern to students of productivity and growth. One of these involves changes in productivity over time; the other involves differences in productivity levels among enterprises, industries, and countries at a given time. Within these frameworks are many problems and subproblems, each of which may lead to a different selection and emphasis of variables.

Explanations of long-term productivity changes in a country, region, or industry usually stress technological

Changes in long-term productivity

change and, as an adjunct, changes in the quality and quantity of capital. Other variables are regarded as playing a passive role and are subordinate. The justification for this is that change in technological knowledge and the capital embodying it is both essential to substantial gains in productivity and the factor most immediately associated with those gains. It ordinarily is perceived as the leading and moving force in the process. When technological change occurs, the quality of capital improves and the amount available to aid each worker usually increases. The kinds of raw materials used may change, with better grades being required or the use of lower grades becoming possible. Changes occur in the way productive factors are organized and production is carried on. Although in some periods and in some circumstances work may have become harder and more tedious following technological advance and although the transition from land to factory has often entailed special hardships, the dominant trend has been toward shorter hours and a diminution of the arduousness of labour.

Emphasis on technological change and capital accumulation as primary forces arises also from a recognition that they are essential and unique to large and systematic advances in productivity. Those gains that can be obtained solely through a reorganization of work or the use of better raw materials or the breakdown of restraining attitudes or practices may occasionally be dramatic, but they are always limited. By contrast, very substantial gains can follow in the wake of growing technological knowledge and increasing supplies of capital. If allowance is made simply for adaptive changes in other factors, the prospects for advance become almost unlimited. Only these two factors can fairly be singled out as constituting the engines of productivity growth.

It has been noted that both the quantity of capital and its quality change as productivity increases, and it is not possible adequately to separate the two in terms of their effects. Increases in capital per worker through the accumulation of more and more of the same kinds of equipment and tools would not lead continuously to proportionate or more than proportionate increases in output per worker. They would, after a point, lead to diminishing increases and eventually even to a decline in output per worker. The onset of a decline would be far distant in an industry or economy possessed of a high level of technical knowledge but starting near the bottom of the accumulation ladder and affected by an acute scarcity of capital instruments. But an ultimate decline would be expected.

Qualitative changes in capital, reflecting advances in knowledge and skill and leading to the design and construction of improved capital instruments, offer an escape from this principle. If capital can be steadily improved over time, its expansion need not entail diminishing returns. In countries for which data from broad sectors and many individual industries are available, there is a rough correlation between growth in the quantity of capital per worker and increases in labour productivity.

MEASUREMENT OF PRODUCTIVITY

As a prelude to an examination of productivity trends over time, this section considers various methods of measuring the output and input components of productivity ratios and some of the difficulties and limitations of the resulting estimates.

Output. With respect to output, ideally the numbers of units of each category of tangible commodity or service should be counted in successive time periods and aggregated for the firm, industry, or total economy in terms of some indicator of relative importance, usually price or cost per unit as of a particular period. The unit value "weights"—price, cost, or other—must be held constant for two or more periods being compared so that changes in aggregate output reflect changes in physical volumes rather than in prices. An alternative procedure that produces the same results with ideal data is to "deflate" current values of the various items produced by index numbers that reflect relative price changes in order to eliminate the effects of price changes. Price deflation is usually employed to obtain estimates of real gross product by sector and industry to be used as numerators of productivity ratios. For tangible industrial production measures, quantities of the various commodities are generally weighted together by constant unit values.

Unfortunately, in most countries data on quantities and prices for many outputs of the finance and service industries are deficient. In the broader real gross product estimates, changes in outputs of a portion of such services are approximated by estimating changes in inputs. Estimates so derived are not suitable for productivity measurement, however. They impart a downward bias to estimates of real product and productivity for the services sector and its affected components and hence for the economy as a whole.

Output of services

Other problems in estimating output arise in adjusting estimates of outputs to take account of quality change, measuring quantities or prices of nonstandard custom-made products, and estimating outputs of nonmarket goods and services. Partial adjustments for quality changes may be made when increases in real costs per unit are associated with the improvements. But it is generally agreed that physical-volume or real-product measures fail to capture at least part of the improvements in product quality, as distinguished from relative shifts among alternative qualities (price-lines) of a given product. Methods of estimating changes in the physical volume of custom-built products, such as buildings or other major structures, have improved in recent years. But changes in the output of nonmarket goods and services, such as those of governments, households, and nonprofit institutions, must generally be measured by changes in inputs. In consequence, productivity estimates are usually confined to the predominant business (enterprise) sector of an economy.

Inputs. Labour input is relatively easy to measure if one is content to count heads of persons engaged in production or, preferably, hours worked. But in fact, the available hours data often relate to hours paid for, rather than hours worked, and these tend to rise in relation to hours at the workplace as the number of paid holidays and leaves are increased. Official estimates generally do not differentiate among various categories of labour. But some academic economists measure labour inputs by occupation and/or industry and possibly other categories and weight the aggregate in each category by a measure of the average compensation in some designated base period. As the average levels of education, training, skills, and experience of workers increase, the weighted measures rise relative to unweighted measures of labour input. Change in the ratio of the two indicates change in the quality of labour input, which is an important part of the explanation of change in productivity.

Capital input is usually assumed to change in the same direction as and proportionally to changes in the real stocks of structures, equipment, inventories, and natural resources. The rates of return on those capital goods in some base period are taken to be indicative of their productivity for the purpose of weighting them together with other factor inputs. Some analysts adjust the capital estimates to take into account changing rates of utilization of capacity; otherwise, changes in utilization rates are reflected in the productivity estimates.

Interindustry purchases and sales of intermediate products—those materials, energy, and other services that are consumed in the production process—are accounted for on a value-added basis and cancel out in the national income and product estimates by industry (one industry's output being the next one's input). But if intermediate purchases are counted as an input for comparisons with gross output estimates, they are measured in the same manner as described for outputs.

HISTORICAL TRENDS

Early industrialization. For most of humanity's history, advances in technology, productivity, and real income per capita came very slowly and sporadically. But with the development of modern science in the 17th century and the quickening of technological innovation that it sparked, the stage was set for significant improvements in productivity. The gains remained modest until the latter part of the

19th century. For the first 50 years after the beginnings of the Industrial Revolution in Britain around 1760, labour productivity grew at an average annual rate of around 0.5 percent, but it then accelerated to more than 1 percent in the 19th century. In the United States it increased at an average rate of 0.5 percent until after the Civil War.

By the latter part of the 19th century the countries of western Europe, the United States, and Japan enjoyed a marked and sustained rate of improvement in productivity generally exceeding that of Britain, the earlier leader.

Growth of GDP

Growth of real gross domestic product (GDP) per hour worked in the western European countries and Japan averaged 1.6 percent from 1870 to 1950, while growth in the United States averaged 2 percent from 1870 to 1913 and almost 2.5 percent from 1913 to 1950. (See Table 1). Data for 10 additional industrialized countries indicated that much the same range of productivity growth rates prevailed for the smaller western European countries and for Canada and Australia. But much of the rest of the world had not yet begun to experience sustained growth of productivity and real per capita income.

Two percent per year may not seem an impressive number, but when compounded over a century it results in more than a sevenfold increase. The sustained and significant increases in productivity of industrialized countries beginning in the latter part of the 19th century were one of the most momentous developments in modern history, and it became much more widely diffused in later decades.

Why did the acceleration begin in the late 19th century? The great improvements in transportation and communications that were made possible by the inventions of the steam and internal-combustion engines and the telephone and wireless communications led to a major expansion of trade, both domestic and international. The British example of free trade led to some liberalization by other countries. By the turn of the century, an increasing number of large companies were beginning to conduct purposeful programs of research and development so that invention and innovation became commonplace and even expected. Educational levels rose, and business schools were founded to teach the new science of management. The growth of per capita income itself tended to raise saving rates, and investment in new plants, equipment, and natural resource development rose substantially. Finally, the growth of productivity in agriculture and increased labour mobility made possible the enormous expansion of manufacturing and, later, the service industries.

Growth of productivity in countries other than the United States accelerated greatly after World War II. The five-country average rate of growth in labour productivity (Table 1) more than tripled in the 1950–73 period compared with the preceding 80 years. After 1973 productivity growth fell by almost half in the five countries, on average, but remained well above the earlier rate. The deceleration was greater in the United States.

Before trying to explain these trends, see Table 2, which summarizes productivity changes from 1950 through a more recent year for a larger number of industrialized countries, and then see Table 4, which shows estimates for groups of countries composing most of the world.

In the 12 countries other than the United States shown in Table 2, real GDP per employed person grew between

1950 and 1973 at an average rate of about 4 percent, about double the rate for the United States. From 1973 to 1979 the average rate decelerated to 2.2 percent a year for the 12 industrialized nations and to virtually zero in the United States. But after 1979 (and especially after 1981) the U.S. rate accelerated significantly, while the 12-nation average rate fell further to 1.8 percent, which was nevertheless still well above the U.S. rate of 0.8 percent a year.

Convergence of growth rates

During the entire period after 1950 there was a significant convergence of rates of productivity growth among the industrialized nations, as shown in Table 3. The average real GDP per person for the 11 countries rose from about 44 percent of that in the United States in 1950 to almost 80 percent in 1986. Furthermore, there is a significant negative correlation between the 1950 levels and the 1950–86 rates of productivity growth—those countries that started farthest behind grew most rapidly in productivity. There had already been some tendency toward convergence among the industrialized nations before 1950, but it was much stronger during the golden quarter-century following World War II.

Table 3: Real Gross Domestic Product per Employed Person

Of even wider importance, most nations outside the original industrialized group also began to record substantial increases in labour productivity beginning around 1950 (see Table 4). What fragmentary information is available indicates that generally low rates of productivity growth were the norm in those countries before 1950. So World War II was a true watershed, in that after the immediate postwar period of reconstruction, most nations were able to accelerate their productivity gains markedly. Those nations, constituting all but about 5 percent of the world's population, could entertain the prospect of attaining, by or before the close of the 21st century, a standard of living comparable to that in industrial Europe in the 1980s. This prognostication assumes that productivity will continue to grow at least at post-1970 rates.

Table 4: Real Gross Domestic Product per Economically Active Person
(1950, 1970, and 1980 in 1975 international dollars and average annual percentage rates of change)

	1950	1970	1980	1950–70	1970–80
Developing market economies	1,176	2,252	3,004	3.3	2.9

Source: Irving B. Kravis and Robert E. Lipsey, "The Diffusion of Economic Growth in the World Economy, 1950–80," *International Comparisons of Productivity and Causes of the Slowdown*, ed. by John W. Kendrick (Cambridge, Mass., Ballinger Publishing Co., 1984), Table 3-A3, p. 145. The 1980 estimates were made from Table 3-A1 assuming that labour force participation ratios in 1980 were the same as in 1975.

The country data underlying Table 4 do not indicate a worldwide convergence of productivity levels, although some tendency toward convergence within the several groups is evident. Note that the group of low-income countries had the lowest rates of productivity advance, while the oil exporters and relatively industrialized middle-income countries had the highest rates. Whereas the centrally planned economies had above-average rates of productivity growth in the period 1950–70, after 1970 they fell below average.

The postwar growth surge. The virtually worldwide upsurge of productivity growth after World War II reflects in an important way the increasingly internationalist thinking and policy-making of leaders of the developed nations. The creation of the World Bank and the International Monetary Fund and of the United Nations and associated agencies encouraged and nurtured cooperative international economic and financial relationships. Although an outgrowth of the Cold War, the Marshall Plan unleashed a major effort on the part of the United States to aid in the reconstruction and economic development of the non-Communist world. Part of the plan called for the creation of productivity centres in member countries, which sent productivity teams to the United States to study and facilitate the transfer of advanced technology. Private lending abroad was encouraged in addition to that of the World Bank and other international lending institutions. Regional trade associations were formed to reduce trade barriers among member countries, and liberalization of international trade was promoted more generally by the General Agreement on Tariffs and Trade (GATT). As a result, world trade grew even faster than production, and most significantly it included transfers of advanced machinery and other producers' goods from the United States and other industrialized countries, which helped raise productivity of the purchasing countries.

Effect of the Marshall Plan

Multinational corporations, typically based in the United States, diffused capital and managerial and technical know-how and helped train nationals of their host countries for jobs, often including upper-level positions. International licensing of patents also helped diffuse technology. An increasing proportion of students in U.S. universities, particularly in business and engineering, came from developing countries. International professional associations and journals also aided in the diffusion of knowledge.

An important reason for the narrowing of the productivity gap between the United States and other industrialized nations after 1950 was the differential rates of saving, investment, and growth of capital per worker. In Japan the ratio of gross saving to GDP was nearly one-third, double that in the United States, and in western Europe it averaged nearly one-fourth (due in part to favourable tax laws). This higher rate of saving, creating capital for both private and public investing, was associated with a rapid decline in the average age of structures and equipment in those countries until 1973. The growth of domestic and foreign trade opened up more opportunities for achieving economies of scale in those countries as well. They also benefited more from resource reallocations, particularly the shift of labour out of agriculture and self-employment where the rates of return were lower.

After 1960 the achievement of technological parity with the United States in the ways noted above became the most important factor promoting productivity advance in the other industrial nations and in an increasing number of advanced developing countries. But, as other nations continued to approach the U.S. level of real product per person, there would tend to be greater convergence in levels and rates of growth of productivity. This would be so because innovations requiring those countries to invest in their own research and development would be more costly than technology transferred from abroad.

Decline in productivity growth

The slowdown in productivity growth after 1973 was almost universal. The oil-price shocks of 1973 and 1979 contributed to accelerating inflation in most countries, reducing economic profits and the rate of saving and investment. Some energy-intensive equipment was rendered obsolete. The growth of real research and development expenditures slowed, as did the pace of technological innovation. The beneficial effects of interindustry shifts of resources became less marked. The changing age–sex mix of the labour force tended to reduce productivity growth in the short run, especially in North America. And government regulations to protect the environment and promote health and safety proliferated in the '70s, increasing costs and inputs but not output as it was usually measured.

The reversal in the 1980s of most of those negative factors helped to accelerate productivity growth in the United States. The continued deceleration in other industrialized countries noted above probably reflected a decline in technology transfer from abroad. There appeared to be no reason, however, why the advance of productivity in the developing countries with adequate absorptive capacity might not continue for years to come. (Ma.F./J.W.K.)

Economic planning

The essential idea behind economic planning is that certain key economic decisions should be made, or at least influenced, by some central authority rather than being left to the free play of market forces. By the late 1960s the majority of the world's countries conducted their economic affairs within the framework of a national economic plan. But in the 1980s the theory and practice of economic planning went through something of a crisis. In the developed market economies the rate of economic growth slowed from the very high levels reached in the 1960s and '70s and unemployment rose significantly. At the same time, public confidence in the ability of governments to influence for the better the performance of the economy diminished. As a result, the popularity of national economic plans waned and the scope left to the free play of market forces widened. In developing countries, forms of economic planning practiced earlier yielded disappointing results characterized by the growth of heavy state bureaucracies and inefficient public enterprises. In these countries also, although the role of the state remained preponderant, market forces were increasingly relied upon to improve economic performance. In the Soviet Union and its satellites, the backward state of the economy and widespread examples of waste and inefficiency led to attempts to introduce more market solutions into the process of economic planning. These attempts proved largely unsuccessful, however, and the inherent rigidity of the Soviet economic model proved an important factor in the collapse of Communism in eastern Europe and the Soviet Union itself, beginning in 1989.

THE NATURE OF ECONOMIC PLANNING

Historically, the idea of central economic planning was associated with the criticism of capitalism as a system of anarchy and greed. Marxist critics did not give much thought to how the economy would be run after capitalism had been abolished; most of them professed to see no difficulty in organizing the society that would follow. When in 1917 the new Soviet government found itself the owner of all the means of production, it had no blueprint as to what to do next. The evolution of central economic

planning in the Soviet Union was largely a pragmatic affair; methods were tried and discarded, and new ones were introduced. The decision in 1927 to undertake rapid and large-scale industrialization required the centralizing of control, since only the government could undertake the task of marshaling the productive resources of the country to achieve its ambitious aims.

In western Europe, economic planning is adapted to a diversified economic structure, a dynamic class of business managers, and a long tradition of political and economic liberty. Consequently, although planning implies an extension of the economic responsibilities and activities of the state, the mainspring of economic growth remains the private sector. Only rarely does the state intervene directly in the affairs of individual firms. Economic planning remains indirect and takes the form of collaboration between the public and the private sectors. Producers and consumers are free to adapt their activities to changes in market conditions and relative prices. In the 1980s there was a general trend for governments to sell state-owned enterprises to the public and to reduce the extent of public regulation of particular sectors, such as air transport.

Communist methods of planning after the mid-1950s entered a state of flux, and the highly centralized administrative type of planning inherited after World War II from the Soviet Union by all the newly established Communist states underwent considerable modifications. In Yugoslavia planners followed policies very different from those of the Soviet model, and differences also emerged in the practice of other eastern European countries. In the Soviet Union itself, a debate concerning the most appropriate means for implementing plans went on for some years, but, despite numerous efforts on the part of the government to reorganize the machinery of planning, the fundamental drawbacks of central economic planning were never overcome. The Soviet Union's attempts in the late 1980s to reform its planning machinery had the unintended effect of bringing down the whole structure of central economic planning, and with it the Soviet government itself. By the early 1990s the post-Communist governments of eastern Europe and of the states of the former Soviet Union had begun making a painful transition to the diversified economic structure typical of the economies of western Europe.

In the meantime, the knowledge of the Soviet-bloc countries' long-standing difficulties had given rise in many developing countries to a repugnance to Soviet planning methods, while the methods used in the developed non-Communist countries were felt to be not directly applicable, either. There was consequently no settled planning doctrine in the developing countries, and the approach of governments remained empirical. In practice, this meant that the state played a major role in setting up new industries and in modernizing agriculture, particularly in countries of recent independence. The state budget was a major source of savings, supplemented frequently by the local currency counterpart of foreign aid. But the absence of a highly qualified civil service placed limits upon the extent and efficacy of state action. Thus, in urban areas, privately owned businesses continued to supply most local consumer goods. In agriculture, peasant proprietorship or large private estates—particularly for export products—remained the general rule. (Jo.Hac./Ed.)

ECONOMIC PLANNING IN COMMUNIST COUNTRIES

Soviet improvisations

Planning in the U.S.S.R. The kind of economic planning that was practiced in the Soviet Union and in most other Communist countries until the 1990s had developed during the 1920s and '30s in the struggle to industrialize the U.S.S.R. The Bolsheviks had seized power in 1917 without any clear notion as to how an economy should be run. No guidance was to be found in the writings of Karl Marx other than the assertion that a socialist society would operate the economy for the common good, which suggested that it would create organs of economic administration to replace the market system of capitalism. In the future Communist society there would be no money, no profit motive. No wages would be necessary to stimulate effort. It would be "from each according to his ability, to each according to his needs." Economics, a science of exchange relationships or value, would wither away or be replaced by a kind of higher management. The Bolshevik leader N.I. Bukharin wrote in 1920:

> As soon as we deal with an organized national economy, all basic "problems" of political economy, such as price, value, profit, etc., simply disappear . . . , for here the economy is regulated not by the blind forces of the market and competition but by the consciously implemented plan.

The leader of the Bolsheviks, Vladimir Lenin, shared these somewhat utopian expectations. It is not clear from his pre-1917 writings just what kind of economic organization he had in mind for Russia should he achieve power. As it turned out, the Russian Revolution of October 1917 was accompanied by economic breakdown, a refusal of cooperation from officials and managers, civil war, and uncontrollable inflation. Partly under the stress of these circumstances, partly from ideology, the Bolsheviks moved to establish thoroughgoing state control over industry and trade, nationalized all economic property including land, declared all private enterprise illegal, and demanded that the peasants deliver all farm surpluses to state procurement organs. Money lost all value.

On paper, this period of War Communism, as it is now called, was one of centralized planning. All economic units, except the peasant producers, were subjected to orders from the government's Supreme Council of National Economy (V.S.N.Kh.). But this initial essay in planning was a failure—except insofar as it facilitated the concentration of the few available resources for the civil war fronts. Rationing functioned spasmodically, there was famine, and output fell drastically.

From Lenin to Stalin

The controversies of the 1920s. In 1921 Lenin introduced the New Economic Policy (NEP). Small-scale private manufacturing, private trade, and free sale of peasant surpluses became legal once again, while the state retained the "commanding heights" (*e.g.*, large-scale industry, foreign trade, banking, transport). The state sector continued to be operated under the aegis of V.S.N.Kh. by trusts and enterprises with state-appointed managers. In 1921 the State Planning Committee (Gosplan) came into existence to advise the government and its economic alter ego, the Council of Labour and Defense, but planning was still a shadowy process. Trusts and enterprises had considerable autonomy and were free to make agreements and grant credits to one another. The planners made forecasts, and government policy decisions influenced the level and direction of state investments; but there was no integrated system of production and allocation planning, even in the state sector, while the private sector was not directly planned at all. In 1924 only 35 percent of the national income, 1.5 percent of agricultural production, less than half of all retail trade, and three-quarters of industrial output were "socialized"; the rest was private.

In 1926–28 a vigorous discussion raged about the future basis of planning. Two schools of thought developed, one advocating "genetic" and the other "teleological" planning. The former, composed of the more moderate and cautious planners, believed that plans should be based on existing trends in the economy and reasonable projections thereof. The latter considered that drastic measures were necessary to speed up the industrialization of the country, and this "teleological" school produced extremely ambitious drafts of the First Five-Year Plan. The radicals conceived the plan as taking precedence over all previous economic decisions so as to enable a sharp break with the past. With the support of the Soviet leader Joseph Stalin, it was their view that won.

Priority for heavy industry

The First Five-Year Plan. The First Five-Year Plan (1928–1932), which was later said to have been carried out in four years, called for immense investments in heavy industry; for example, steel output was to be more than doubled by 1932. Amid great confusion, the planning mechanism was overhauled, and gradually a "command economy" was established. In this system, subordinate units of the economy (*e.g.*, industrial enterprises) operated in accordance with administrative instructions, and they did not decide their inputs or outputs by negotiation with other enterprises, these being determined by the planners.

The sole effective criterion of management decision became conformity to plan—*i.e.*, to the instructions issued by the central administrative planning organs. In this way, the political authorities achieved a high degree of control over resource allocation and were able to enforce their priorities. Consequently, when the First Five-Year Plan ran into trouble, the government was able to insist on the fulfillment of most of the plans for key sectors of heavy industry, at the cost of a drastic fall in availability of consumers' goods.

The structure of the Soviet planning system. A rearrangement of the planning system was the necessary consequence of the new tasks it was called upon to perform. In 1932 three People's Commissariats (for heavy, light, and timber industries) replaced the V.S.N.Kh.; these were further split, and by 1939 the industries of the U.S.S.R. were run by 21 People's Commissariats (the numbers varied in subsequent years). Each commissariat (renamed ministry in 1946) controlled a branch of industry, either directly or through a ministry in one of the union republics. The ministries issued instructions to "their" enterprises, organized the supply of materials and components, and also disposed of the output.

Control from the top

At the apex of the system stood the leaders of the Communist Party, who decided the policy objectives in economic as in other matters and who made choices as to the means of achieving those objectives. All key appointments in the economic hierarchy were made or confirmed by appropriate party committees.

The work of Gosplan. It was Gosplan's task to "translate" the politically determined objectives into a consistent set of plan targets. There had to be coherence between production and supply at all times, as well as between investment plans and the current production of capital goods. Foreign trade also had to be taken into account, as a drain on available resources (exports) and as a source of needed goods (imports). The planners proceeded by drawing up a series of material balances, which expressed anticipated supply of, and demand for, all key commodities. The successive versions of the plan were revised until a general balance was attained, since it was no use planning an increase in production of any item if the necessary additional machinery, raw material, and fuel could not be made available. The task was of special complexity in the short term (*i.e.*, within a period of a year), since the plan had to take the form of millions of consistent instructions to thousands of enterprises to produce, deliver, transport, and process millions of commodities of a great many shapes, sizes, and types.

Balancing supply and demand

Needless to say, all these decisions must be made somewhere in all economic systems. The Soviet type of "command economy" developed under Stalin, however, provided no criterion for decentralized decision making such as is provided, however imperfectly, by the market mechanism in Western capitalist countries. Consequently, the coordination of all these decisions had to be consciously achieved by the planners. In practice much depended on proposals from below, since the planners suffered from information overload. The actual plans were necessarily aggregated (*e.g.*, tons of metal, millions of square metres of cloth, millions of rubles' worth of construction or of furniture), so that decisions on the product mix were necessarily decentralized. The resultant malfunctioning came to be much criticized in the Soviet press. Quality was often sacrificed in order to fulfill the plan in quantitative terms; planned targets expressed in tons, for example, encouraged excessive weight in the product concerned, while targets expressed in rubles discouraged economy and rewarded the use of expensive materials. Plan-fulfillment as a dominant criterion of success stimulated management to conceal their productive potential so as to get an "easy" plan, while fears of supply shortages encouraged hoarding. Soviet critics increasingly pointed to the rigidity of prices, which did not reflect supply–demand conditions. The planners claimed that it was their task, not that of the price mechanism, to ensure balance between supply and demand, but the enormous complexity of their task made it impossible for them to do so.

Low growth rates in the late 1970s and early '80s, on top of continued shortages and corruption, alarmed the Soviet leadership. Many proposals were aired as to how the system might be changed. A series of reforms were in fact promulgated (notably in 1965 and 1974), but these were soon criticized as having been inconsistent and halfhearted.

The Gorbachev reform agenda. The program of reform proposed and undertaken in the period 1987–90 under the leadership of Mikhail Gorbachev represented a truly radical change in the nature of the Soviet system, the first since the early 1930s. In this program it was intended that the bulk of the product mix would be decided not by the planners but by management, in negotiation with their customers or with the wholesale-trade organs. The need for competition was explicitly recognized, both between state enterprises seeking customers and between them and newly legalized cooperatives (more or less free enterprises). Enterprises were to be protected by law against arbitrary exactions by their superiors. An end was decreed to "soft" credits and subsidies, leaving open the real possibility of bankruptcy. Large enterprises were to be allowed direct access to foreign markets.

Reforms along these lines were gradually introduced, but some formidable obstacles proved impossible to surmount. One was chronic shortage, which continued to stimulate hoarding and compelled the continuation of material allocation. Prices were only slowly and with difficulty reformed. The declared aim of speeding up growth led to the survival of growth targets, in the familiar units of rubles, tons, and square metres, although the reformers aimed to abolish such targets. The priority of centrally determined objectives was assured by the system of so-called *gos-zakazy* (state orders), and these could cover the major part of the output of many enterprises. There were, moreover, serious problems of ideology (the enhanced role of the market came into conflict with traditional Marxist views) and bureaucratic resistance. Deeper reforms that were proposed threatened the fundamental powers of the Communist Party and its officials. In the meantime, the central government watched its authority over economic decision making steadily erode at the republic and regional levels, largely owing to Gorbachev's more liberal policies. Central economic planning ceased to have any meaning as many enterprises, effectively freed from government oversight, tried to cope in an economy that as yet lacked the free play of market mechanisms. With the collapse of the Soviet central government in late 1991, economic policy-making devolved upon Russia and the other newly independent republics of the former union, most of whom appeared committed to a diversified economic structure in which central planning would play a much-reduced role.

Agricultural planning. Agricultural planning in the Soviet Union had a peculiarly difficult history. With priority given to industrialization, agriculture during the regime of Stalin was essentially treated as a source of cheap food and materials for the cities. The peasants were, in fact, expropriated by force in the period 1930–35, and the bulk of them were compelled to join collective farms (*kolkhozy*). While in Soviet ideology state farms, operated like factories with wage labour, were preferred to collective farms, they remained of relatively minor importance until after 1954. Mechanization was for many years confined to a very few crops and especially to grain growing. The entire system was primarily designed to ensure deliveries of produce at low prices, and the planners and administrators concentrated on procurements, while production plans were seldom, if ever, fulfilled. Under Nikita Khrushchev in the late 1950s and early 1960s there was a substantial change of policy, with greatly improved prices and a major investment program designed to restore agriculture to health.

Farm collectivization

This policy was continued under Leonid Brezhnev in the 1960s and '70s. Despite very large investments and higher farm prices, however, output rose slowly and costs rose quickly, necessitating very large subsidies. Peasant incomes rose, but incentives to work on the large state and collective farms were ineffective, and millions of townspeople had to be mobilized annually to help with the harvest. An important reform was the spread within state and collective farms of the use of autonomous work groups that

were paid according to results. In 1987, proposals were adopted that would allow the leasing of land to families over and above the small plots and privately owned livestock that most rural residents had and that even as late as 1986 were producing 25 percent of the Soviet Union's entire agricultural output.

As the authority of the central government crumbled in 1990–91, many state and collective farms gained de facto control over their own affairs, though few used this to any distinct advantage. More profound changes seemed likely as a result of the breakup of the Soviet Union in 1991 and would probably involve the reversion of farmlands to private ownership in some republics.

Planning in other Communist countries. In other Communist-ruled countries the Soviet system was extensively copied, even in minor details, until 1956. After that date much depended on choices made by the party leadership of each country. Both Yugoslavia (in the 1960s) and China (in the 1980s) decentralized control over major sectors of their economies and introduced individual incentives on a significant scale. The Soviet Union's satellites in eastern Europe, by contrast, maintained fairly rigid centralized controls until 1989–90. At that time, the Soviets abandoned their political-military control over the region, and most eastern European countries used the opportunity to begin moving toward a free-market economic system, however haltingly and even painfully.

Poland. Poland's unsound economic policies in the 1970s led to serious domestic imbalances and a growing foreign debt and contributed to the political-economic crisis of 1980–81. Martial law, imposed in 1981, made possible the imposition of a very sharp rise in consumer prices, and the regime then adopted a radical reform designed to greatly strengthen the market mechanism. Its implementation, however, was delayed by the chronic shortages and imbalances inherited from the previous period. It is noteworthy that the bulk of agriculture in Poland remained dominated by private peasant smallholders, who were free to sell what and when they wished. Beginning in 1990, the new post-Communist government of Poland abandoned price controls and subsidies and undertook a major currency reform in a drastic program to convert the Polish economy to a free-market basis. The privatization of the larger state-owned enterprises proceeded relatively slowly, however, as in other eastern European countries.

Czechoslovakia. Czechoslovakia's centralized economic system was in the process of being reformed in 1968, when fears of more fundamental political change brought about Soviet military intervention, which had the side effect of halting the economic reform process. Following the events of 1989–90, Czechoslovakia moved in the same general direction as Poland. State subsidies on many items were reduced, prices were decontrolled, and the private ownership of industrial and commercial enterprises and of farmland was legalized and even encouraged. Larger industrial enterprises were converted to joint-stock companies, and their shares were sold to the public.

East Germany. East Germany's industrial planning was based upon a set of monopolistic cartels (*Kombinate*), which had considerable autonomy in carrying out the tasks of satisfying the needs of domestic customers and of export markets. Perhaps because of traditional German organizational skills and work ethic, the system was more efficient in operation than those of most other countries in the Soviet bloc. It remained woefully inefficient by the standards of the free-market economies of western Europe, however, as became clear following West Germany's historic unification with East Germany in 1990. When deprived of their state subsidies, most eastern German industries proved unable to survive in free competition with those of western Germany or with other European Community countries. As a result, eastern Germany's rapidly shrinking industrial sector quickly came to depend on subsidies from the German government and on massive new plant investment by corporations based in western Germany.

Romania. Of all the Soviet-bloc nations, it was Romania that most fully retained Stalinist methods, both in the economy and in politics, into the 1970s and '80s. Unsound economic policies led to a long-lived situation of crisis and acute shortages, especially of energy and even of food. The resulting widespread deprivation sparked a popular uprising in 1989 that overthrew Romania's longtime leader, Nicolae Ceauşescu. But, as in some other eastern European nations, the end of Communist rule in Romania was followed by a sharp economic decline: the closing of unprofitable state-supported industries resulted in falling production and rising unemployment, while shortages of food and other consumer goods continued and even worsened.

Hungary. In 1968 Hungary adopted a system of market socialism that left each enterprise management very largely free to determine its own production program. The central planners were no longer to set obligatory production targets. While some prices remained controlled, others were set free. Enterprises were also given some freedom to buy and sell abroad, and efforts were made to link Hungarian prices with those on world markets. Profits became the principal measure of managerial success, and bonuses based on profits had an appreciable effect on managers' and workers' incomes. Large-scale investments were still controlled by the central planners, but the enterprises were required to finance roughly 40 percent of all investments out of their own resources.

Market socialism in Hungary

Balance of payments difficulties and internal pressures (*e.g.,* for subsidies to unsuccessful enterprises), however, led to severe strains, and output and living standards stagnated after 1978. Agriculture, however, dominated by genuinely autonomous cooperatives and a flourishing private sector, continued to do well. Hungary also had a sizable "second economy," with a variety of legal small-scale private enterprises.

Yugoslavia. The Yugoslav Communists developed their own conception of socialist planning after their break with Moscow in 1948. The collectivization of agriculture was abandoned in the early 1950s. The control of the state-owned enterprises was given to workers' councils that would decide their own production programs according to profitability, with prices subject to negotiation. Investments were partly controlled by the enterprises themselves out of profits or by the central planners, partly financed from bank credits. But lack of effective central control, and rivalries between national republics, gave rise in the 1980s to a serious economic crisis led by a rapidly rising rate of inflation. These economic difficulties foreshadowed Yugoslavia's breakup in the early 1990s.

China. Chinese Communist planning at first followed the Soviet pattern. In 1958, however, came the Great Leap Forward, an effort to speed up progress by shifting rural manpower into manufacturing. This failed disastrously, and the Chinese Communist leadership had to devise its own planning methods, adapted to a vast country with poor communications and a low stage of economic development. After the social-political cataclysm known as the Cultural Revolution and the death of Mao Zedong, reformers led by Deng Xiaoping came to power in the late 1970s and launched a major shakeup of the system. Agriculture was decollectivized, small-scale private trade and workshops were legalized, and the role of market forces was substantially increased. Larger-scale industry remained subject to central planning controls, though there, too, market-type reforms were experimented with. While there were successes, balance of payments problems and inflationary pressures continued to cause some anxiety. Agricultural output rose sharply at first, but concern over shortfalls in cereals production continued. In China, too, the search went on for the elusive optimal balance between plan and market.

Major reform movement

Assessment of Soviet-type planning. The Soviet type of planning grew up under the special conditions prevailing in the U.S.S.R. and was adapted to the task of speedy industrialization of a poor country, with strong emphasis on heavy industry, explicable partly by the logic of industrialization (steel and machinery are more conducive to industrial growth than textiles and jam), partly by concern for military potential. The system made it easy for the authorities to attain a high rate of forced saving and investment and a rapid buildup of basic industries, though at the cost of neglecting for many years the elementary needs

of the citizens. Insofar as the investment plans of most basic industries depended in the last resort on a quantitative estimate of future demand, the Soviet system was reasonably well adapted to making such estimates, since so much of the additional demand was a consequence of the planners' own decisions.

In practice, of course, Soviet-type planning was not always able to realize these potential advantages. There were repeated instances of overinvestment, followed by the abandonment or freezing of partly finished projects. Experience also showed that the separate administrative units into which a nationalized economy must be divided can take as narrow and short-term a view as any capitalist entrepreneur. Thus, the most easily accessible forests were cut, the richest sources of iron ore exhausted, and fallow land put under the plow in order to fulfill current plans, with little consideration of the consequences. A centralized system of material balances is not insurance against erroneous forecasting. The material-balances approach exercised a conservative influence, perhaps because it was simplest to plan on the assumption that the various technical coefficients would remain constant. Innovation was often resisted, and the influence of user demand was weak. It must be borne in mind, of course, that Western economies also have many imperfections. A theoretical model of centralized planning works as smoothly and as efficiently as a theoretical model of a perfectly competitive market, but neither exists in the real world.

Shortcomings of central planning

Following the death of Stalin in 1953, the Soviet economic system was presented with new problems. It showed itself unable to cope effectively with the finer adjustments required in a sophisticated industrial economy. In particular, the system was not able to stimulate the adoption of new technology despite heavy expenditure on research. It dealt very clumsily with the satisfaction of consumer demand, though this became more important in the changed political conditions, not only in the Soviet Union but also in most of its European allies. The unsuitability of the traditional Soviet planning model in a modern, highly technological, and intensely competitive world economy became painfully clear to the generation of Soviet leaders who came to power in the mid-1980s. But their efforts to incorporate with socialist planning the flexibility and grass-roots enterprise that come with market mechanisms also failed, largely because central planning had become indissolubly tied to the totalitarian structure of state power in the Soviet Union. (A.No./Ed.)

ECONOMIC PLANNING IN NON-COMMUNIST COUNTRIES

Planning in developed countries. Since the end of World War II in 1945, most non-Communist developed countries have practiced some explicit form of economic plan. Such countries include Belgium, Canada, Finland, France, Germany, Ireland, Italy, Japan, The Netherlands, New Zealand, Norway, Portugal, Spain, Sweden, and the United Kingdom. Planning as a focus for economic policy-making in these countries had its heyday in the 1960s and '70s. After that time, although the formal mechanisms for working up the national economic plan remained in existence, their impact upon national economic policy-making was much diminished. Governments harboured narrower ambitions, and public opinion came to expect less from government action.

Origins of planning. Until World War II there was no serious attempt at economic planning outside the Soviet Union. During the Great Depression of the 1930s, many governments were forced to intervene vigorously in economic affairs, but in a manner that amounted to economic warfare; this intervention took the form of giving increased protection to domestic producers against competition from abroad; of acquiescing in the formation of cartels and other arrangements among producers to raise prices and reduce competition; and of higher levels of government spending, some of it for relief and some of it for armaments.

Planning for economic warfare

At the end of the war there was a shift to the left in the politics of some of the countries, and with it a turn to more positive forms of government intervention. In Great Britain the Labour Party secured a large majority in Parliament in 1945, and with it a mandate for policies aiming at more social equality. In Scandinavia, particularly in Sweden, moderate left-wing traditions in government made a transition to planning politically acceptable. In France, left-wing groups, including the Communist Party, emerged as the dominant political force after 1945 with programs of far-reaching social reform. More important, a group of eminent public servants, engineers, and business leaders—continuing a tradition of French 19th-century capitalism known as Saint-Simonianism—were in favour of the state taking a leading role in economic affairs.

While the initial impulse to planning came from the political left, actual decisions by governments to plan were based on practical considerations rather than on political doctrine. The decision to plan most often followed a crisis in a country's economic affairs, as was the case in France after World War II, when there was an urgent need to reconstruct and modernize the economy. In the United Kingdom the setting up of a medium-term plan accompanied the emergency measures taken to deal with a balance of payments crisis in July 1961; and the Labour government's National Plan of September 1965 was formulated in similar circumstances. In Belgium and Ireland dissatisfaction with the past performance of the economy was a major reason for planning. Belgium had not shared in the European prosperity of the 1950s, and accordingly, in 1959, the government adopted a plan aimed at an increase of 4 percent a year in the GNP, practically double the rate achieved from 1955 to 1960. Its planning methods were modeled on those of France.

The French example also influenced planning in other European countries. In Great Britain a Conservative government undertook, during a balance of payments crisis in July 1961, to set up a National Economic Development Council to draft a five-year economic plan that would emphasize much more rapid economic growth. The Netherlands, which had been very successful since the war in achieving balanced economic growth, initiated five-year plans in 1963 through the medium of the Central Planning Bureau, which had for some years been advising on national budgetary policies. Italy had first turned to planning in the 1950s, when a plan for the development of southern Italy was launched; later, attempts were made to extend this example of regional economic planning into a plan for the national economy. Even in West Germany, where the Christian Democratic governments had emphasized a policy of strengthening the free market, a need for some central management of the economy was increasingly recognized.

Economic planning in the developed countries has always been pragmatic rather than inspired by an attempt to apply preconceived ideological doctrines. In the 1980s, governments in most of these countries swung to the right of the political pendulum and were therefore less sympathetic to the idea of economic planning, which therefore took a back seat in national economic policy-making. The problems that the developed countries faced (chiefly slow growth and high unemployment) were thought not to be amenable to more state action. Indeed, the cost of financing government was thought in influential circles to be stifling private initiative. In the same way, many enterprises under public ownership were "privatized" (that is, returned to private ownership), and the scope of government regulation of the economy was notably reduced. In the view of a new generation of policymakers, the major role of government in promoting economic growth was, first, to provide a stable, noninflationary framework for enterprises to make their decisions and, second, to support the emergence of the new "information society" through improved education and technical training and research and development programs.

Objectives of planning. The plans drafted in the developed countries postulate target rates of growth and some indication of the choices to be made in allocating rates of increase to the various kinds of expenditures on available goods and services (private and public consumption, social investment, directly productive investment, stocks, and exports). Further, as the plan has to be balanced, the total of these components of overall demand must fall

Growth, balance, and consistency

within the probable total available supply of goods and services, after allowing for the desired level of the current balance of payments surplus. The rates of increase of some types of demand—directly productive investment and stocks in particular—are fixed within fairly narrow limits by technological considerations once the overall rate of growth of output has been chosen. But an important area of choice concerns the respective rates of growth of private consumption by individuals and what has come to be called collective consumption; *e.g.*, education, health, urban facilities, provision for culture.

Another planning objective that has become very prominent (and that figures in the plans of Great Britain, The Netherlands, France, and Italy, to mention only a few) is the correction of imbalances in regional development.

One of the most important functions of economic planning is to achieve consistency among different economic objectives. Some desirable goals are likely to conflict with others. While it may be possible, for example, to stimulate the economy so as to obtain sharply higher levels of output and employment, the measures required to do this may also produce rapidly rising prices, which in turn will lead to rising imports and falling exports; the result may be a balance of payments crisis.

Public discussions of objectives

Stages of planning. One of the chief merits of national planning is that it publicizes the choices before a country and encourages discussion of them. In France the Parliament is consulted on the broad outline of the five-year plan, which is presented in terms of a number of alternative balanced sets of objectives. More government spending on social services, for example, can be shown as implying a slower rise in individual incomes after taxes, or—a rather more difficult choice to make explicit—a higher growth rate can be shown as requiring greater willingness on the part of producers and consumers to adapt themselves to changes in markets and technology.

In other countries the choice of objectives may be left to the government, which thus makes the plan a part of the program upon which it will stand or fall at the next election. Or the government may prefer to detach itself almost entirely from the plan. In West Germany, where planning is less explicit, projections of economic trends are set out in a technical document that does not have the formal status of a government draft and circulated to the governments of the *Länder* (states) and to employers and trade unions. Such projections are thought to have some influence on public thinking and on the expenditure plans of business and government. In Great Britain, when the Conservatives returned to power in 1970, there was less enthusiasm for public discussion of planning objectives than there was under the preceding Labour government. The Dutch procedure is to leave the main responsibility for drafting projections of economic trends to the Central Planning Bureau. In that country, however, business and labour have generally been ready to take account of such projections when drawing up their own plans. In Belgium, after the period of strained relations between the main language groups during the 1960s, regional considerations have been very much to the fore in all planning discussions.

An important issue for the European countries in the late 20th century has been the impact on their economies of the European Economic Community (Common Market) and the aim of achieving a single, unified market by 1992.

Bringing the public into the planning process

Since targets in this type of planning do not constitute orders to producers and consumers to do or not to do particular things, the plan has to take account of what private firms say they intend to do, or could do, during the period of the plan. Drafting a plan, therefore, requires arrangements for bringing the representatives of the private sector—both employers and workers—into the planning process. This is usually done by setting up a tripartite body (the High Planning Council in France, the Council for Economic Planning in Sweden, for example) where representatives of the private sector are brought together with representatives of the government.

Government departments in most countries draft programs several years in advance for expenditure on such public projects as education, road building, urban improvement, and hospital construction. But it often happens that these programs are not mutually consistent. One of the advantages of an overall plan is that the confrontation and coordination between the various programs has to be done in an explicit manner. The task can be difficult; watertight administrative compartments are not always easy to break down.

Efforts to incorporate into the plan all that can be known about the intentions of the private and public sectors need to be supplemented by more general economic analysis. As has been stressed already, the plan should be, above all, coherent; and the best way of ensuring this is to build up the planned targets within the framework of the national income accounts. Since World War II, such accounts have been drawn up on an annual basis in all the developed countries. From this it is only a step to projecting the national accounts for several years ahead.

Innovations in planning

Earlier types of economic planning leaned heavily upon the method of economic balances. This consists of setting out the quantities of economic resources that will be available during the plan period and comparing them with the quantities demanded by the plan. Four balances are of key importance: the demand for and supply of goods and services; of savings; of manpower; and of foreign exchange. The notion of balance is a valuable one in planning, since no plan can be successful if it outruns the available resources. The method has its difficulties, however, because of the numerous interactions among different sectors of the economy, with the consequence that an adjustment in one set of balances requires adjustments in the others—a complex and time-consuming process. The method of balances is also unable to throw light upon a more fundamental aspect of economic decision making, the need to choose among alternative courses of action on their own merits.

Other methods of planning that have in varying degree replaced the method of balances include mathematical model making and cost–benefit analysis. A mathematical model consists of a series of equations that describes the structure and working of the national economy, enabling various sets of targets to be "tried out" by feeding their values into a computer. It is too early, however, to claim for economic models any clear superiority over the more pragmatic method of economic balances. The most systematic use of models has been in The Netherlands and France. In the Scandinavian countries, a strong mathematical tradition among economists has favoured their adoption.

Cost–benefit analysis, sometimes known as the planning–programming–budgetary system (PPBS), represents an effort to improve the planning of government expenditures. Starting from the fact that public expenditures are not sensitive to the economic considerations of price and profitability but that they nevertheless use up scarce resources that have economic value, PPBS attempts to provide rules of calculation when deciding upon the allocation of these resources. A first step is to break down public expenditure into its main functions and to divide each of the latter into programs that can be identified with government policy objectives. Then an effort is made to evaluate the effectiveness of each program in achieving its declared objectives, together with a consideration of alternative ways of achieving the same objectives and the costs of those alternatives. The U.S. government pioneered in the application of PPBS to government activities in the 1960s. Great Britain introduced it in the Ministry of Defence in the late 1960s and then began to extend it to other departments, particularly in education and science. In France the government decided to apply the system in 1968, first in the Ministry of Defense and then in relation to energy, town planning, and such departments as posts and telegraph. By the early 1970s PPBS had become an integral tool of national economic planning.

In their planning, all the non-Communist countries leave a large margin of initiative to individual producers and consumers; *i.e.*, they rely upon market mechanisms rather than upon direct controls. There is no contradiction between this state of affairs and the existence of a plan. First, as already noted, the fact of associating the private

Problems of flexibility

sector with the drafting of the plan encourages its representatives to be dynamic in their behaviour, a prerequisite for any successful growth policy. Second, when a plan is drafted in this way, all sectors are encouraged in making their own plans to adopt the same general assumptions about the growth of the economy. In France this aspect of planning is called "generalized market research." Third, participation in drafting the plan can help to make the representatives of the employers and workers more conscious of existing obstacles to growth and encourage them to find constructive solutions for overcoming them.

But the government is not freed from participating actively in carrying out the plan. The government's budget and its monetary policy must be used in such a way that overall demand rises as steadily as possible along the desired growth path. The problem of avoiding checks to growth caused by balance of payments difficulties is likely to call for special attention.

Direct government intervention

There is no easy solution to the problem of how to reconcile five- or six-year plans with the need to adjust economic policy to the phases of the business cycle. In Japan, a country that has experienced several sharp though brief recessions since the end of the postwar reconstruction period, governments are willing to cut back their public expenditure programs and to take restrictive fiscal and monetary measures because they believe that the economy will soon rebound once the restrictive measures have done their work. Japan's remarkable economic growth has borne out this confidence. In the less flexible economies of western Europe, governments are more circumscribed in their action. France, Germany, and The Netherlands have instituted systematic reviews of their plan targets every one or two years and are quite prepared to revise the targets if necessary. In addition to these general measures for implementing plans, some governments attempt to influence more directly the behaviour of private firms by granting depreciation allowances for investments and tax exemptions for some activities, such as expenditure on research.

But it is in the field of regional development policy that governments intervene most actively to influence the decisions of the private sector of the economy. There is widespread use in western Europe of tax incentives and grants from public funds to encourage private firms to expand in less-developed regions. Frequently, permission to set up a new factory, or to expand an existing one, in already congested areas where labour shortages are acute is refused. In addition, governments endeavour to stimulate growth in the less-developed areas by improving transport facilities, housing, and urban infrastructure generally. These efforts have not shown any significant success in raising incomes or reducing unemployment in the less-developed regions. This does not mean that the regional policies have been without effect, however, for without them the regional disparities might have worsened. Present-day plans for regional development attempt to concentrate on a few selected "growth points" where it is thought that favourable geographic characteristics or the presence of raw materials or other advantages offer the most hope of success.

Assessment of planning. By the 1970s planning had become more flexible and selective than in earlier years, and the trend continued and even accelerated in the 1980s.

Economic growth as an object of policy

The general consensus was that the government should seek to create the fundamental conditions that would encourage growth; this would include measures to establish and maintain competition. The corollary was that governments should try to avoid applying detailed controls over the private sector in peacetime, since these lead to reduced efficiency.

Some critics of planning have charged that the planners put too much emphasis on measures to accelerate economic growth, overlooking the social costs involved. A difficulty with simple growth targets is that they do not measure the increase in side effects such as pollution, noise, and the destruction of nature; on the contrary, they show the expenditures on combating these effects as part of the growth itself. (For example, expenditures on conservation or smog abatement are included in the statistics of national income and GNP.) Similar contradictions are found in the easy equation of economic growth with the general welfare: it is possible for income per head of the population to rise while the incomes of certain groups fall; quite frequently, some groups, such as the aged, handicapped, unemployed, and certain ethnic groups, do not share in the increasing prosperity of their country. The general welfare obviously includes elements such as health, housing, education, and economic opportunity as well as economic growth. This concern with the qualitative aspects of economic growth has left its mark upon the objectives written into the economic plans, which increasingly spell out general social aims.

Governments have also adopted a more flexible approach to the setting of targets. During the 1960s, mainly under the influence of French practice, targets for the private sector were often spelled out in detail. But experience showed that elaborate targets were rarely achieved, although they were likely to be considered by public opinion as representing firm commitments by the government. Since then, care has been taken to distinguish between firm targets and estimates. The firm targets are set only for areas over which governments have a considerable degree of control. While the government may have some influence on output in manufacturing industry, this depends more directly upon such things as the state of business conditions abroad, the purchasing habits of consumers, trends in prices and incomes, and so on. It is noteworthy that Japan, which holds the record for economic growth since World War II, has never used detailed output targets in its multiyear plans. (Jo.Hac.)

Planning in developing countries. Since the end of World War II, it has become an accepted practice among the governments of the developing countries to publish their "development plans." These are medium-term plans, usually for a five-year period. The aim is to select a period long enough to include projects spanning a number of budget years but not so long as to delay periodic assessment of the development effort stretching over a series of plans. The development plan attempts to promote economic development in four main ways: (1) by assessing the current state of the economy and providing information about it; (2) by increasing the overall rate of investment; (3) by carrying out special types of investment designed to break bottlenecks in production in important sectors of the economy; and (4) by trying to improve the coordination between different parts of the economy. Of these, the first and fourth are perhaps the most important and the least understood function of economic planning. The other two functions of planning cannot be efficiently carried out without ample and reliable information, nor without effective economic coordination between the different government departments and agencies within the public sector and the private sector. In most developing countries, information about the economy is scarce, and planning has provided the impetus to acquire and analyze the necessary data in order to provide a better understanding of the functioning of the economy. In order to improve coordination it is necessary to spread reliable economic information to indicate the future course of the government's economic intentions and activities so that the people concerned, both in the public and the private sectors, may make appropriate plans of their own to bring them in line with the government's plan. In fact, this may be regarded as the main reason for publishing development plans, although this point is not always clearly appreciated by the governments that issue them.

Why poor countries plan

Approaches to development planning. The newly independent countries, just starting to plan their economies, usually begin with a simple type of development plan. In most cases this is merely an ad hoc list of individually conceived social and economic projects that the various government departments have submitted for the plan. So long as the projects are well selected (say, to break some obvious bottlenecks in production) and are well designed in a technical sense, such a simple plan may be quite serviceable. But it tends to suffer from a number of weaknesses arising from insufficient coordination. (1) Since the projects are drawn up on a piecemeal basis in separate

From simple to comprehensive planning

government departments, there is usually no systematic attempt to compare the relative costs and benefits of the plans proposed by the different departments on a uniform basis. As a consequence, the collection of projects included in the plan may or may not represent the most productive pattern of investing the available resources of the government. (2) A lack of coordination frequently leads to wasteful duplication and a failure to take advantage of complementary relationships between individual projects. (3) A simple listing of the projects does not provide a clear-cut system of priorities in their implementation. Typically, the projects that are relatively easy to implement are pushed far ahead of others that, although requiring a longer time to prepare and implement, may have the potential to contribute more directly to the expansion of national output and government revenue. This can have serious budgetary consequences when the projects that are easier to implement generally happen to be in the field of social welfare, education, and health and—although they may indirectly contribute to economic development in the longer run—entail a significant and ever-increasing stream of recurring government expenditure after their completion.

An obvious way of remedying these defects is to formulate a more systematic plan of the public investment program as an integrated whole. In order to do this, it is necessary to begin by making a careful estimate of the total amount and time pattern of the financial resources that the government expects to receive during the plan period from domestic sources and from external loans and aid. Next, it is necessary to make realistic estimates of the costs and benefits of the alternative investment projects within the public sector as a whole so as to select the most productive combination of projects, taking into account significant complementary relationships between the different projects. In selecting the best combination of projects to be included in the plan, it is necessary to pay special attention to the time pattern of costs and benefits. A poor country, with limited sources of government revenue, would have to discount future benefits heavily relative to the more immediate benefits and would have to give priority to the type of project with quicker returns in the form of expansion in output and tax yields over the type of project that may promise higher rates of return, but only in the more distant future.

The problems of carrying out an integrated public investment program serve to emphasize the crucial role of the annual budget in development planning. At the aggregate level, with a given amount of external aid, the stream of the total investable funds available to the government during the plan period depends on its ability to raise revenue (and borrow from domestic sources) and, equally important, to control its nondevelopment, or "consumption," expenditure year by year during the plan period. At the individual project level, the fact that a project requires a number of budget years to complete does not dispense with the need for annual budgetary controls to ensure that it is being implemented in stages, according to the timetable as originally planned. Indeed, it is only through the discipline of annual budgetary controls that a medium-term development plan is likely to be kept nearer the course as originally planned.

Few developing countries have submitted themselves to the budgetary discipline necessary for implementing an integrated public investment program. This has not deterred them, however, from jumping from a simple type of development plan to "comprehensive" economic planning, embracing both the public and the private sectors and regulating both the aggregate level of economic activity and its detailed composition. The drive toward comprehensive planning arises from various causes: from a distrust of the automatic working of the market mechanism and its ability to promote economic development; from a desire to assert national economic independence by government control of foreign trade and investment; and from the theories of economic development, fashionable during the 1950s, that emphasize the need for a "big push" to overcome technical indivisibilities and the need for a simultaneous setting up of a number of mutually supporting projects to enjoy the benefits of technical complementaries. The economic development plans published by the developing countries in the 1960s were fairly elaborate. The trend to "quantitative" planning encouraged the use of elaborate statistical estimates and projections even when the primary statistical sources on which these computations were based were often unreliable or conjectural. Advanced mathematical techniques were also increasingly employed.

Planning the whole economy

Basically, there are three parts to such a development plan: (1) the target figures for increase in per capita income and consumption to be attained at the end of the plan (with estimated figures for the intermediate years during the plan); (2) estimates of the quantities of various resources, such as capital, manpower, and foreign exchange, needed to implement the target figures (including the time profile of the rate at which these resources will be required during the plan); and (3) parallel but independent estimates and projections of the quantities and the time pattern of these resources expected to be available both to the government and to the economy as a whole during the plan period. The elaborate planning documents issued by some developing countries may be described as attempts to quantify as far as possible the information required under the three heads and to test the formal consistency of the plan. This essentially consists in asking (a) whether the total amount of available resources is sufficient to meet the total requirements of resources as set by the target figures, and (b) whether the allocation of resources planned for different sectors is consistent with the detailed target figures for the increased output of different goods and services required for consumption and investment. When the resources required by some industries are intermediate goods (the output of other industries), input–output tables are frequently used to check whether the outputs of different industries are sufficient to supply not only the target figures for final use in the form of consumption and investment but also the "indirect use" required by other industries. The more advanced planning models using programming techniques in an attempt to solve the further question (c) whether the planned pattern of allocating resources is the most efficient; *i.e.,* whether it minimizes the resources needed to meet the target figures as compared with other patterns.

Difficulties in development planning. In spite of increasing professionalism in the formulation of development plans on paper, the practical performance of the developing countries in implementing development plans of any complexity has not been very encouraging. Development plans, however elaborately formulated on paper, rarely get beyond the first and most obvious practical hurdle, namely, how to equate the total amount of investable resources required to fulfill the target rates of economic development set by the plan with the total supply of investable resources. This arises from the practice of starting with some minimum "politically acceptable" target rate of economic growth while optimistically assuming that the problem of providing the necessary resources will somehow look after itself. This is the opposite of realistic planning, which should start from the supply of available resources and find out the maximum possible rate of economic growth that can be got out of these resources. There also appears to be a tendency to be overly optimistic as to the availability of resources and to underestimate the costs of projects. Very often, development plans have been cut short in midstream as balance of payments difficulties arising from this optimism have led the authorities to curtail their efforts sharply. Sometimes, also, the plan may be deliberately drawn up larger than can be sustained out of the available domestic resources as an elaborate window-dressing exercise to obtain a greater amount of external aid. When external aid fails to fill the planned gap in resources, the typical reaction is not to reduce the size of the plan but to take the politically less painful (and the administratively simpler) expedient of keeping to the publicly declared target rates of the plan and then trying to fill the gap in resources out of "forced saving," which it is hoped will be generated by budget deficits and inflation. Unfortunately this "forced saving" approach has not worked in most developing countries, because the

The need for realistic targets

public soon loses confidence in the stability of the purchasing power of money as prices tend to rise in step with increases in government expenditure. The pressure of domestic inflation increases the pressure of demand for imports, while rising domestic production costs discourage expansion of exports.

This disequilibrium situation may be eased by raising the rate of interest to reduce the demand for investable funds and to encourage saving, and by devaluation of the currency to discourage imports and encourage exports. Some governments have done so. But many governments in developing countries generally prefer to maintain artificially low rates of interest and to supply cheap loans to the public sector and to some favoured sections of the private sector engaged in modern manufacturing industry. Many are also reluctant to devalue for fear of further raises in prices through speculation and the higher costs of imported goods. Thus many tend to rely heavily on detailed administrative controls and import licensing to ration the scarce supply of investable funds and foreign exchange. The attempt to control the entire economy in detail through a network of direct administrative controls inevitably results in inefficiency and delays, aggravated by the inadequacy of the administrative machinery and a shortage of competent civil servants. The closer the "integration" planned between different sectors of the economy, the greater the damage to efficient coordination, since delay in one sector causes widespread delays in others.

The main weaknesses of the formal "quantitative" economic development plans are that they distract attention from a variety of important qualitative factors and focus on physical quantities rather than incentives. Qualitative factors include such matters as the practical capacity of the administrative machinery to implement the plan, the degree of political stability, and the extent of public confidence in the government's willingness and ability to carry out stated aims, which are crucial for the practical success of planning. Focus on physical quantities seems to result from a perceived need to indicate target levels of output of individual commodities; it distracts from the important fact that much economic activity is undertaken within the private sector and is responsive to incentives. Plans have tended to induce efforts to implement controls over private-sector activities. These have been effective to a large extent in preventing unplanned production activities, but they have been less effective in inducing desired increases in output without the appropriate incentives. The developing countries might do much better with a less comprehensive type of planning, making a greater use of indirect controls through the market mechanism and concentrating attention on the breaking of bottlenecks, particularly to the expansion of production in agriculture and export industries. Some developing countries have in fact succeeded in attaining rapid rates of growth just by concentrating on these vital sectors of the economy without an elaborate paraphernalia of planning.

(H.My./A.O.K.)

Economic forecasting

Economic forecasting is the prediction of any of the elements of economic activity. Such forecasts may be made in great detail or may be very general. In any case, they describe the expected future behaviour of all or part of the economy and help form the basis of planning.

The importance of theory

Formal economic forecasting is usually based on a specific theory as to how the economy works. Some theories are complicated, and their application requires an elaborate tracing of cause and effect. Others are relatively simple, ascribing most developments in the economy to one or two basic factors. Many economists, for example, believe that changes in the supply of money determine the rate of growth of general business activity. Others assign a central role to investment in new facilities—housing, industrial plants, highways, and so forth. In the United States, where consumers account for such a large share of economic activity, some economists believe that consumer decisions to invest or save provide the principal clues to the future course of the entire economy. Obviously the theory that a forecaster applies is of critical importance to the forecasting process; it dictates his line of investigation, the statistics he will regard as most important, and many of the techniques he will apply.

Judgment in forecasting

Although economic theory may determine the general outline of a forecast, judgment also often plays an important role. A forecaster may decide that the circumstances of the moment are unique and that a forecast produced by the usual statistical methods should be modified to take account of special current circumstances. This is particularly necessary when some event outside the usual run of economic activity inevitably has an economic effect. For example, forecasts of 1987 economic activity in the United States were more accurate when the analyst correctly foresaw that the exchange value of the dollar would fall sharply during the year, that consumer spending would slacken, and that interest rates would rise only moderately. None of these conclusions followed from purely economic analysis; they all required judgment as to future decisions. Similarly, an economist may decide to adjust an economic forecast that was made by traditional methods to take account of other unique conditions; he may, for example, decide that consumers will alter their spending patterns because of special circumstances such as rising prices of imports or fear of threatened shortages.

Although judgment may be based on experience and understanding, it may also be no more than unconscious bias. Forecasts based on judgment cannot be subjected to the kind of rigorous checks applied to forecasts developed by the use of more objective techniques. Consequently, the most accurate and useful forecasts are likely to be those founded on essentially economic considerations and standard statistical techniques. Though they can then be modified by the application of judgment, the resulting changes should be stated explicitly enough so that anyone wishing to use a forecast will know where, and how, it has been affected by the forecaster's own judgment, or bias.

Economic forecasting is probably as old as organized economic activity, but modern forecasting got its impetus from the Great Depression of the 1930s. The effort to understand and correct the worldwide economic disaster led to the development of a vastly greater supply of statistics and also of the techniques needed to analyze them. After World War II, many governments committed themselves to maintaining a high level of employment. Most governments of the industrialized Western countries were prepared to intervene more often and more directly in economic affairs than previously. Business organizations manifested more concern with anticipating the future. Many trade associations now provide forecasts of future trends for their members, and a number of highly successful consulting firms have been formed to provide additional forecasting help for governments and businesses.

TYPES OF FORECASTING

Forecasting the GNP and its elements. Perhaps the forecasts most familiar to the public are those of gross national product and its elements. Gross national product, or GNP, is the total value of the goods and services produced in a nation. It is, therefore, a convenient and comprehensive measure for assessing changes in general economic welfare. A forecast of the GNP also provides a useful framework for more detailed forecasts of specific industries. Almost all developed nations maintain sets of national income accounts and make forecasts as well.

The GNP can be regarded as being composed of three major components: spending by government, private investment spending, and spending by consumers. Net exports (that is, exports minus imports) are also counted in the GNP but their magnitude, which may be positive or negative, is usually small. (For the nations that depend more heavily on foreign trade, like Japan after World War II, or that incur substantial imbalances in their trade accounts, like the United States in the 1980s, net exports are of course more important.)

Forecasting government spending

Government spending is usually the easiest part of the GNP to forecast. Government expenditures can be determined with a fair degree of accuracy for well over a year in advance by studying existing budgets and appro-

priations, modified to take account of new political or economic developments. Most such adjustments are relatively minor for any forecast that runs only a year or two into the future; new government programs usually have only a small effect on expenditures in the short run. An obvious exception to this is a major change in the military situation, which can drastically alter spending plans.

It is important to note that government spending, as counted in the GNP, is not the same as total budgeted expenditures. Spending gets into the GNP only when money is paid for goods—military equipment, buildings, and so on—or services, which principally means the wages and salaries of government employees. These kinds of expenditures account for only part of the government budget; the remainder represents money transferred to bondholders, other private citizens (particularly people receiving pensions), and state and local governments. These funds affect the GNP only when they are finally spent by the recipients.

Forecasting private investment

Private investment poses far more difficult forecasting problems because it reflects many thousands of individual and corporate decisions that are not recorded publicly (as government budgets are) and that can be, and often are, changed very substantially. Private investment is the most erratic of the major categories of the GNP—the most subject to "boom and bust" cycles. A good forecast of investment spending is therefore essential to an accurate appraisal of the overall economic situation.

Capital investment by business (spending for new plants and equipment) is particularly important. The incomes generated in the process of manufacturing new equipment and building new plants play a major role in increasing consumer spending during periods of expansion. But when investment slumps, employment and incomes generally also suffer, slowing the entire economy. Business investment has thus been studied with great care, and a wide variety of methods to guide forecasters have been developed, including econometric models, surveys of business investment plans, regular reports on commitments for investment, and fundamental studies of the condition of the nation's stock of capital goods (see below *Forecasting techniques*).

Business also invests in inventory—that is, goods in the process of production and finished goods not yet sold to the final consumer. Most of the time, inventories increase roughly in line with the trend of sales. If sales fall short of expectations, however, inventories tend to become excessive. Business then moves to reduce stocks by cutting back production. Such cutbacks can aggravate economic recessions; as production is reduced because of disappointing sales, incomes are thereby reduced and sales fall further, inventories must be cut even more, and so on in a downward spiral. Consequently, correct forecasts of inventory investment are both essential to good economic forecasting and also particularly difficult. Surveys of business plans to build or reduce inventory have been helpful; econometric methods have also been applied; but inventory investment remains one of the weak links in the forecasting process.

New home construction accounts for a relatively small share of the GNP, but it is important to the forecaster because home construction is a relatively volatile industry. Homebuilding activity responds quickly to changes in the availability of mortgage money from the principal mortgage lending institutions, and thus forecasters follow closely the flow of savings to these institutions and also the level of commitments that have been made to finance future construction. Information on the number of building permits issued is also helpful, as are statistics on the volume of new construction contracts.

Forecasting consumer spending

Economists used to believe that forecasting consumer spending was fairly simple; as a rule of thumb, consumers could be counted on to spend 94–95 percent of their current income and save the rest. Thus an analyst could calculate the amount of personal income generated by government spending, private investment, and past consumer spending, adjust for tax payments, and arrive at a good estimate of consumer spending. This method still works well in determining the average rate of spending over an extended period of time. But in rich countries consumers as a group are quite free to vary their spending patterns in the short run; they may at any particular time spend more than usual because they anticipate shortages or because they believe that their incomes will rise further; or they may cut back their spending if they fear that a recession is about to develop. Such variations from normal spending patterns have their main effect on durable goods such as automobiles and household appliances; spending is far more stable for nondurables (food, clothing, and the like) and for services.

Because consumers account for such a large proportion of all economic activity, a shift of just 1 or 2 percent between spending and saving can make the difference between rapid growth or recession for the entire economy. Economists now use surveys of consumer attitudes in attempting to read the mood of the public; surveys of intentions to buy durable goods have also been helpful.

Forecasting for an industry or firm. General economic conditions set the tone for all parts of the economy. Good forecasting for an industry or firm begins, therefore, with a good analysis of the overall economy. Within this framework, the analyst must then take account of the particular factors that are most important to his own industry. In some cases, the sales of an industry may correlate fairly directly with one or more of the elements of the national income and product accounts—lumber sales with home construction, for example, or sales of nondurable consumer goods with consumer income and total consumer spending. Forecasting for industries that produce basic materials usually requires a series of projections for specific markets. A steel forecast might be based on the outlook for such major steel markets as automobiles, construction, and metal containers. The basic forecast would then be adjusted for expected shifts in exports and imports of steel and for changes in inventories of steel or steel-using products.

Forecasting is most difficult for companies that produce durable goods such as automobiles, industrial equipment, and appliances and for companies that supply the basic materials for these industries. This is because sales of such goods are subject to extreme variation. In a five-year span in the early 1970s, annual sales of automobiles in the United States increased by 22 percent in one year and declined by 22.5 percent in another. Consequently, the durable goods industries in general and automobile companies in particular have developed especially complex and sophisticated forecasting techniques. In addition to careful analysis of income trends (based on a general economic forecast), automobile companies, which are particularly sensitive to competition from imports, support a number of studies of consumer attitudes and surveys of intentions to purchase automobiles.

Forecasting for an individual firm obviously begins with a forecast for the industry or industries in which it is involved. Beyond this, the analyst must determine the degree to which the company's share of each market may vary during the forecast period. Such variations can result from the introduction of a new product, the improvement of an existing product, the opening, closing, or expansion of plants, the activities of domestic or foreign competitors, a change in sales effort, or a variety of other factors. Information required to make such assessments may come in part from the company's own investment and marketing plans. Information on the activity and sales prospects of competitors is frequently collected from the firm's own salesmen. An increasing number of companies now employ sophisticated market research techniques to determine the probable reaction of their customers to new products.

Long-term forecasting. In recent years, increasing effort has been devoted to long-range forecasting for periods extending five, 10, or more years past the normal "short-term" forecast period of one or two years. Business has come to recognize the usefulness of such forecasts in developing plans for future expansion and financing.

Labour force projections

Long-range forecasts usually are based on the assumption that activity toward the end of the period will reflect normal "full" employment. Given this assumption, the overall rate of growth depends on two principal factors:

the number of people in the labour force and the rate at which productivity (output per worker) increases. The number of people of working age is known, barring some natural disaster (and excluding immigration), far into the future; they have already been born. Forecasters usually assume that productivity will continue to grow at the typical rates of recent decades. Expected technological developments, however, may alter the projected rate of change. The combination of changes in the labour force and productivity produces an estimate of the total growth rate for the economy.

A measure of total economic activity arrived at by such methods as these serves, in effect, as a control total for making long-range forecasts of the constituent elements of the economy. If estimates for spending by consumers, government, and business add up to more than the total of goods and services that can reasonably be expected, then the projection for one or more of these elements must be reduced. If the sum of the projected parts is less than the probable total, the analyst is likely to assume a shift in economic policy that will move the economy up to full employment by the end of the forecast period and adjust his various projections up to the appropriate total.

Long-range forecasts for individual parts of the economy depend on many of the same factors as do short-range forecasts, except that cyclical factors are usually ignored. Over the longer range, however, additional factors enter. Among the most obvious of these are growth in the population and shifts in its age composition. Changes in age composition have had a major effect on both consumer and government spending patterns in many countries since World War II. The unusually large age cohorts born in the years following World War II had enormous influence on patterns of consumption and on labour-force composition. As young adults they tended to buy large amounts of durable goods and to add to the need for home construction; on the average, they saved less and borrowed more in relation to their incomes than most older people had. Their children constituted a secondary "baby boom," who could expect to see their parents become the largest generation of retired persons ever known.

In addition to population pressures, a number of other trends and assumptions influence long-range forecasts. Assumptions about war and peace are obviously critical. Assumptions must be made about government spending programs; expensive new programs may bring higher taxes and less consumer spending, whereas slower growth in government spending may lead to tax reductions. Over longer periods of time, technological discoveries or changes in financial institutions can affect the overall economy. When the forecast is made for an industry or a firm, the expected introduction of new products is also important.

FORECASTING TECHNIQUES

Economic forecasters have a vast array of information to work with and a growing variety of techniques. A few economists, believing that just one or two key factors determine the future course of the economy, limit their observations to these factors and develop forecasts based on them. A leading example of this is found in the school of thought that ascribes most importance to changes in the money supply. But most economists use a wider range of material.

Information on spending. Some elements of the future are known with reasonable accuracy. Government spending is reflected in existing budgets. These budgets indicate how much will be spent and how much money will be extracted from the stream of private spending by taxation. Similar information is available on some parts of the private economy. Periodic surveys conducted both by government and by private organizations measure business plans to invest in new plants and equipment. Increasingly, attempts are made to probe the mood and intentions of consumers concerning the possible purchase of automobiles, houses, appliances, and other durable goods. Regular surveys are also made to determine the general mood of the public—whether people are optimistic or pessimistic about their own economic future and thus whether their spending is apt to be relatively strong or relatively weak.

Surveys of business and consumer intentions

In general, such information obtained from the various surveys of investment plans, spending plans, and attitudes has been highly useful to economic forecasters. Such information helps to limit the range of possibility. But plans and attitudes change, sometimes quite abruptly, and although the surveys are useful tools they are not clear and reliable guides to the future.

Selection of turning points. Probably the single most difficult economic forecasting problem is to pick the turning points in economic activity—the times at which the economy turns from growth to recession or from recession to recovery. Because of the difficulty and importance of the problem, major efforts have been made to develop tools for this purpose. The National Bureau of Economic Research in the United States has identified a number of statistical series that normally turn up or down before the economy does. Common stock prices, business inventories, and changes in consumer installment debt are among these series, which are known as "leading indicators." Other statistical series normally move in line with overall activity ("coincident indicators"), and a third group changes direction after the economy does ("lagging indicators"). Although careful study of these groupings of statistics can be helpful, unfortunately there is no fixed relation between the movements of the economy and those of the various indicators. Although the "leading indicators" do ordinarily lead, the length of the lead varies. This reflects the dynamic nature of a complex economy that is constantly changing and in which strength or weakness may come from a variety of sources.

Some economists also use sets of statistics called diffusion indexes to calculate economic turning points. A diffusion index is a method of summarizing the common tendency of a group of statistical series. If a greater number of the series are rising than are declining, the index will be above 50; if fewer are rising than declining, it will be below 50. In effect, a diffusion index measures the degree to which either strength or weakness pervades the economy. If, for example, most of a group of industries are increasing their production rates, the economy as a whole is probably expanding; if the proportion of industries that are growing begins to decline and falls significantly below 50 percent for a period of time, the economy is probably in a recession, or at least moving in that direction.

Econometric methods

Economists frequently use mathematical equations to express the normal relations between various economic factors. As a simple example, a given increase in consumer income will ordinarily produce a certain increase in sales, saving, and tax revenue, and these developments can be expressed mathematically. With a sufficient number of equations, all the important interactions within the economy can be simulated in a mathematical model. With the advent of computers able to make millions of calculations in a few moments, economists began to construct more and more complex sets of equations, called econometric models. These models, some of which include hundreds of equations, can be used to forecast overall economic activity (macroeconomic forecasting) or developments in particular parts of the economy (microeconomic forecasting). The success of econometric forecasting has so far been limited because the exact nature of economic relations is not fully known, and also because of the inadequacies of existing statistics. Nevertheless, the improvement of these techniques represents the greatest hope for more accurate economic forecasting in the future.

Input–output analysis

The computer has also stimulated development of another potential forecasting tool, input–output analysis. Input–output tables show the relations between the various industries and sectors of an economy. They show, for each industry, the amount of its output that goes to every other industry to be used as raw materials or semifinished products, as well as the amount that goes to the final markets of the economy. Input–output tables also show each industry's consumption of the products of other industries, as well as each industry's contribution to the production process. With such a table it is possible to trace the effects of changes in one industry or sector upon all the other industries and sectors.

The usefulness of input–output analysis for forecasting

purposes has been limited by a number of factors. One problem is that it takes years to put such complex sets of statistics together; in a changing economy, relations may have shifted by the time the data for a base period have been assembled. Progress has been made, however, in developing methods to bring these relations (called technical coefficients) up to date, and input–output analysis shows increasing promise as a forecasting tool.

THE ACCURACY OF ECONOMIC FORECASTS

Major improvements have been made in the accuracy of economic forecasting. A competent economist can usually predict accurately enough to provide guidance to those who make policy decisions. Consensus forecasts—the average of a group of forecasts made by different individuals or organizations—have come closer and closer to the mark in recent years. Errors persist, nevertheless, and they occasionally lead to bad decisions.

Sources of error

The sources of error in economic forecasts are many. Some lie outside the realm of economic analysis; wars, agricultural or other natural disasters, or political upheavals are examples. Some forecasts go wrong for essentially ideological reasons: people who do not believe that an economic system will function tend to forecast its failure, which accounts for the many predictions of another great depression. Adherents of a political party in power have a notable tendency to optimism, whereas their opponents, including economists, tend to view the future with alarm. The student of forecasts must obviously consider their source; purity of motive is an important virtue for economists.

The most vexing sources of error, however, lie within the realm of economic knowledge. Many are statistical. Not only are some of the published data inaccurate but even the best statistics are available only after a period of time; the forecaster is forever predicting the future when he cannot be completely sure of the present. Statistics of inventories, among the most volatile economic elements, are noteworthy in this respect.

The most persistent form of error in economic forecasting, however, is probably theoretical. Man's knowledge of his own economic institutions is limited. Good analysis is made more difficult by the fact that these institutions are constantly changing. This means that economic theory based on experiences of the 1950s may be of limited use in the 1980s. Some of the greatest contributions to the continued improvement of economic forecasting may come from economists who are not necessarily forecasters themselves but have the insight to understand the changing economy of today. (R.W.E.)

Economic planning: (*Planning in Communist countries*): General works on Soviet-type planning include ALEC NOVE, *The Soviet Economy*, 3rd ed. (1986); PAUL R. GREGORY and ROBERT C. STUART, *Soviet Economic Structure and Performance*, 3rd ed. (1986); MICHAEL ELLMAN, *Socialist Planning* (1979); MARIE LAVIGNE, *The Socialist Economies of the Soviet Union and Europe* (1974; originally published in French, 1970); TREVOR BUCK and JOHN COLE, *Modern Soviet Economic Performance* (1987); DAVID A. DYKER, *The Future of the Soviet Economic Planning System* (1985); ABRAM BERGSON and HERBERT S. LEVINE (eds.), *The Soviet Economy: Toward the Year 2000* (1983); and P.J.D. WILES, *Economic Institutions Compared* (1977). For historical background, see ALEC NOVE, *An Economic History of the U.S.S.R.* (1969, reprinted with revisions, 1982); and the highly detailed and well-documented survey of the creation of the system in EDWARD HALLETT CARR and R.W. DAVIES, *Foundations of the Planned Economy, 1926–29*, 3 vol. in 5 (1969–76). For a discussion of Mikhail Gorbachev's reform program, see ABEL AGANBEGYAN, *The Challenge: Economics of Perestroika*, trans. from Russian (1988). Fundamental theoretical discussions are offered in JÁNOS KORNAI, *Economics of Shortage*, trans. from Hungarian, 2 vol. (1979, reissued 1980); V.V. NOVOZHILOV, *Problems of Cost-Benefit Analysis in Optimal Planning* (1970; originally published in Russian, 1967); JOSEPH S. BERLINER, *The Innovation Decision in Soviet Industry* (1976); and on a more empirical level, RONALD AMANN, JULIAN COOPER, and R.W. DAVIES (eds.), *The Technological Level of Soviet Industry* (1977).

On social policy, see ALASTAIR MCAULEY, *Economic Welfare in the Soviet Union* (1979). On foreign trade, see FRANKLYN D. HOLZMAN, *Foreign Trade Under Central Planning* (1974); and PHILIP HANSON, *Trade and Technology in Soviet-Western Relations* (1981). Analyses of agricultural development include

STEFAN HEDLUND, *Crisis in Soviet Agriculture* (1984); D. GALE JOHNSON and KAREN MCCONNELL BROOKS, *Prospects for Soviet Agriculture in the 1980s* (1983); and KARL-EUGEN WÄDEKIN, *Agrarian Policies in Communist Europe* (1982). More general works on socialist planning are WŁODZIMIERZ BRUS, *The Economics and Politics of Socialism* (1983); ALEC NOVE, *The Economics of Feasible Socialism* (1983); and BRANKO HORVAT, *The Political Economy of Socialism: A Marxist Social Theory* (1982). On other eastern European countries, see DAVID GRANICK, *Enterprise Guidance in Eastern Europe: Comparison of Four Socialist Economies* (1975); LJUBO SIRC, *The Yugoslav Economy Under Self-Management* (1979); and JÁNOS KORNAI, *Contradictions and Dilemmas: Studies on the Socialist Economy and Society* (1986; originally published in Hungarian, 1983), on Hungary. On the background to Chinese reforms, see MARK SELDEN and VICTOR LIPPIT (eds.), *The Transition to Socialism in China* (1982).

(A.No.)

(*Planning in developed countries*): A historical introduction to the development of economic planning in western Europe is provided in M.M. POSTAN, *An Economic History of Western Europe, 1945–1964* (1967). A major technique of planning is discussed in HAROLD A. HOVEY, *The Planning-Programming-Budgeting Approach to Government Decision-Making* (1968). Techniques of measuring social aspects of economic growth are explored in ELEANOR BERNERT SHELDON and WILBERT E. MOORE (eds.), *Indicators of Social Change: Concepts and Measurements* (1968). Later assessments of the appropriate role of government with respect to planning include SAMUEL BRITTAN, *The Role and Limits of Government: Essays in Political Economy* (1983, reissued 1987); LEO PLIATZKY, *Paying and Choosing: The Intelligent Person's Guide to the Mixed Economy* (1985); and ALICE M. RIVLIN (ed.), *Economic Choices 1984* (1984). A general survey of problems faced by governments in improving overall economic performance is given in *Structural Adjustment and Economic Performance* (1987), a collection of data prepared for the Organisation for Economic Co-operation and Development.

(Jo.Hac.)

(*Planning in developing countries*): A good introduction to the theory and practice of economic planning in the developing countries is W. ARTHUR LEWIS, *Development Planning: The Essentials of Economic Policy* (1966), which illustrates the various stages of drawing up a consistent development plan but also emphasizes that sound fundamental economic policies are more important than formal planning techniques. ALBERT WATERSTON, *Development Planning: Lessons of Experience* (1965, reissued 1974), is a well-documented survey of development plans in various countries, particularly good in discussing the various administrative and fiscal problems of development planning. WOLFGANG F. STOLPER, *Planning Without Facts: Lessons in Resource Allocation from Nigeria's Development* (1966), is a case study with a pragmatic and general approach to development planning. Later research includes WILLIAM R. CLINE and SIDNEY WEINTRAUB (eds.), *Economic Stabilization in Developing Countries* (1981), essays on a range of topics; DAVID BEVAN *et al.*, *East African Lessons on Economic Liberalization*, (1987); a study of the effectiveness of economic incentives; PAUL M. LUBECK (ed.), *The African Bourgeoisie: Capitalist Development in Nigeria, Kenya, and the Ivory Coast* (1987), a study of the current state of African economies; and NORMAN GEMMEL (ed.), *Surveys in Development Economics* (1987), a review of contemporary opinion on the subject.

(H.My./A.O.K.)

Economic forecasting: Various of the economic indicators commonly used for forecasting are surveyed in KENNETH C. LAND and STEPHEN H. SCHNEIDER (eds.), *Forecasting in the Social and Natural Sciences* (1987); JOHN LLEWELLYN, STEPHEN POTTER, and LEE SAMUELSON, *Economic Forecasting and Policy—the International Dimension* (1985); and GEOFFREY H. MOORE, *Business Cycles, Inflation, and Forecasting*, 2nd ed. (1983). Techniques for selecting appropriate data and models for use in economic forecasting are discussed in GILES KEATING, *The Production and Use of Economic Forecasts* (1985); LAWRENCE R. KLEIN and RICHARD M. YOUNG, *An Introduction to Econometric Forecasting and Forecasting Models* (1980); STEVEN C. WHEELWRIGHT and SPYROS MAKRIDAKIS, *Forecasting Methods for Management*, 4th ed. (1985); and NORMAN FRUMKIN, *Tracking America's Economy* (1987). One of the most useful sources of timely statistical data for U.S. economic forecasts is *Survey of Current Business* (monthly).

(R.W.E./Ed.)

Economic Systems

Economic systems refer to the ways in which humankind has arranged for its material provisioning. One would think that there would be a great variety of such systems, each corresponding to the many cultural arrangements that have characterized human society. Surprisingly, that is not the case. Although a wide range of institutions and social customs have been associated with the economic activities of society, only a very small number of basic modes of provisioning can be discovered beneath this variety. Indeed, history has produced but three such kinds of economic systems—those based on the principle of tradition, those organized according to command, and the rather small number, historically speaking, in which the central organizing form is the market.

The very paucity of fundamental modes of economic organization calls attention to a central aspect of the problem of economic "systems"; namely, that the objective to which all economic arrangements must be addressed has itself remained unchanged throughout human history. This unvarying objective is the coordination of the individual activities associated with provisioning—activities that range from hunting and gathering in primitive societies to administrative or financial tasks in modern industrial systems. What may be called "the economic problem" is the orchestration of these activities into a coherent social whole—coherent in the sense of providing a social order with the goods or services it requires to assure its own continuance and to fulfill its perceived historic mission.

Social coordination can in turn be analyzed as two distinct tasks. The first of these is the production of the goods and services needed by the social order, a task that requires the mobilization of society's resources, including its most valuable and most resistive resource, human effort. Of nearly equal importance is the second task, the appropriate distribution of the product. This task must not only provide for the continuance of society's labour supply (even slaves must be fed) but must also accord with the prevailing values of different social orders, all of which favour some recipients of income over others—men over women, aristocrats over commoners, property owners over nonowners, or party members over nonmembers.

All modes of accomplishing the basic tasks of production and distribution rely on social rewards or penalties of one kind or another. Tradition-based societies depend largely on communal expressions of approval or disapproval. Command systems utilize the open or veiled power of physical coercion or punishment, or the bestowal of wealth or prerogatives. The third method—the market—also brings pressures and incentives to bear, but the stimuli of gain and loss are not usually within the control of any one person or group of persons. Instead, they emerge from the "workings" of the system itself, and, on closer inspection, those workings turn out to be nothing other than the efforts of individuals to gain pecuniary rewards by supplying the things that others are willing to pay for.

There is a paradoxical aspect to the manner in which the market resolves the economic problem. In contrast to the conformity that guides traditional society or the obedience to superiors that orchestrates command society, behaviour in a market society is mostly self-directed and seems, accordingly, an unlikely means for achieving social integration. Yet, as economists ever since Adam Smith have delighted in pointing out, the clash of self-directed wills becomes converted into just such a means within the setting of competition that is an indispensable legal and social precondition for a market system to operate. The unintended outcome of this competitive engagement of self-seeking individuals is the creation of the third, and by all odds the most remarkable, of the three modes of solving the economic problem.

Not surprisingly, these three principal solutions are distinguished by the distinct attributes they impart to their respective societies. The coordinative mechanism of tradition, resting as it does on the perpetuation of social roles, is marked by a characteristic changelessness in the societies in which it is dominant. Command systems, on the contrary, are marked by their capacity to mobilize resources and labour in ways far beyond the reach of traditional societies, so that societies with command systems typically boast of large-scale achievements such as the Great Wall of China or the Egyptian pyramids.

The third of the systems, that in which the market mechanism plays the role of energizer and coordinator, is in turn marked by yet another historical attribute, resembling neither the routines of traditional systems nor the highly personalized achievements of command systems. The mark of the market is the galvanic charge imparted to economic life from the energies unleashed by its competitive, gain-oriented setting. This charge is dramatically illustrated by the trajectory of capitalism, the only social order in which the market mechanism has played a central role. In *The Communist Manifesto,* published in 1848, Karl Marx and Friedrich Engels wrote that in less than a century the capitalist system had created "more massive and more colossal productive forces than have all preceding generations together." They also wrote that it was "like the sorcerer, who is no longer able to control the powers of the nether world whom he has called up by his spells." That creative, revolutionary, and often disruptive capacity of capitalism can be traced in no small degree to the market system that performs its coordinative task.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 531, and the *Index.*

This article is divided into the following sections:

HISTORICAL DEVELOPMENT OF ECONOMIC SYSTEMS

Primitive economic systems. Although economics is primarily concerned with the modus operandi of the market mechanism, an overview of premarket coordinative arrangements is not only of interest in itself but also throws a useful light on the distinctive properties of market-run societies. The earliest and by far the most historically numerous of economic systems has been that of primitive society with its central order-bestowing agency of tradition. Such economic forms of social organization must be far more ancient than Cro-Magnon man, and a few are still preserved in Eskimo tribes or bands of Kalahari hunters or Bedouin tribespeople. So far as is known, all tradition-bound peoples solve their economic problems today much

as they did 10,000 years or perhaps 10,000 centuries ago—adapting by migration or movement to changes in season or climate, sustaining themselves by hunting and gathering or by slash-and-burn agriculture, and distributing their output by reference to well-defined social claims. Elizabeth Marshall Thomas describes this distributive system in *The Harmless People:*

> It seems very unequal when you watch Bushmen divide the kill, yet it is their system, and in the end no person eats more than the other. That day Ukwane gave Gai still another piece because Gai was his relation, Gai gave meat to Dasina because she was his wife's mother. . . . No one, of course, contested Gai's large share, because he had been the hunter. . . . No one doubted that he would share his large amount with others, and they were not wrong, of course; he did.

Subsistence in primitive economies

Besides the inertial property that is perhaps the outstanding attribute of these primitive economic societies, two further aspects deserve attention. The first concerns their level of subsistence, long deemed to have been one of chronic scarcity and want. According to the still controversial findings of the anthropologist Marshall Sahlins this is not true. His studies of several primitive peoples found that they could easily increase their provisioning if they so desired. The condition usually perceived by nonprimitive observers as scarcity is felt by them as satiety: Sahlins describes primitive life as the first "affluent society."

A second attribute of interest in primitive economic systems is the difficulty of describing any part of their life activities as constituting an "economy." No special modes of coordination set the activities of hunting or gathering, or the procedures of distribution, apart from the rest of social life, so that there is nothing in Kalahari or Eskimo or Bedouin life for which there is needed a special vocabulary or conceptual apparatus called "economics." The economy as a network of provisioning activities is completely absorbed within and inextricable from the traditional mode of existence as a whole.

Centralized states. Very little is known of the origin of the second of the great systems of social coordination, namely the creation of a central apparatus of command and rulership. From dimly perceived clusters of population, impressive civilizations emerged in Egypt, China, and India during the 3rd millennium BC, bringing with them not only dazzling advances in culture but also the enormously powerful instrument of state power as a new moving force in history.

The appearance of these centralized states is arguably the single most decisive alteration in economic, and perhaps in all, history. Although tradition still exerted its stabilizing and preserving role at the base of these societies—Adam Smith said that in "Indostan or ancient Egypt . . . every man was bound by a principle of religion to follow the occupation of his father"—the vast temple complexes, irrigation systems, fortifications, and cities of ancient India and China, or of the kingdoms of the Inca and Maya, attest unmistakably to the difference that the organizing principle of command brought to economic life. It lay in the ability of centralized authority to wrest considerable portions of the population away from their traditional occupations and to use their labour energies in ways that expressed the wishes of a ruling personage or small elite.

Herodotus recounts how the pharaoh Khufu used his power to this end:

> [He] ordered all Egyptians to work for himself. Some, accordingly, were appointed to draw stones from the quarries in the Arabian mountains down to the Nile, others he ordered to receive the stones when transported in vessels across the river. . . . And they worked to the number of a hundred thousand men at a time, each party during three months. The time during which the people were thus harassed by toil lasted ten years on the road which they constructed, and along which they drew the stones; a work, in my opinion, not much less than the Pyramids.

Creation of economic surplus

The creation of these monuments illustrates an important general characteristic of all systems of command. It is that such systems, unlike those based on tradition, can generate immense surpluses of wealth—indeed, the very purpose of a command organization of economic life can be said to lie in the generation of such a surplus. Command systems thereby acquire the wherewithal to change the conditions of material existence in far-reaching ways. Until the modern era, when command has become the main coordination system for socialism, it was typical of such systems to use this productive power principally to cater to the consumption or to the power and glory of their ruling elites.

Moral judgments aside, this highly personal disposition of surplus has the further consequence of again resisting any sharp analytical distinction between the workings of the economy of such a society and that of its larger social framework. The methods of coordination that create and distribute wealth in a command system are identical with those that guide the imperial state in all its historical engagements, just as in primitive society the methods that coordinate the activities of production and distribution are indistinguishable from those that shape family or religious or cultural life. Thus, in command systems, as in tradition-based ones, there is little or no need for a special kind of social analysis called economics.

Preconditions for market society. These general considerations throw into relief the nature of the economic problems that must be resolved in a system of market coordination. Such a system must be distinguished from the mere existence of marketplaces. Marketplaces have existed far back in history. Trading relations between the ancient Levantine kingdoms and the pharaohs of Egypt in about 1400 BC are known from the tablets of Tell el-Amarna. A thousand years later Isocrates boasted of the thriving trade of classical Greece, and a rich and varied network of commodity exchange, as well as a well-established market for money capital, were prominent features of classical Rome.

These flourishing institutions of commerce testify to the ancient lineages of money, profit-mindedness, and mercantile groups, but they do not testify to the presence of a market system. In premarket societies, markets were the means to join suppliers and demanders of luxuries and superfluities, but they were not the means by which the provision of essential goods and services was assured. For these purposes ancient kingdoms or republics still looked to tradition and command, utilizing slavery as a basic source of labour (including captives taken in war) and viewing with disdain the profit orientation of market life. This disdain applied particularly to the use of the incentives and penalties of the market as a means of marshaling labour. Aristotle expressed the common feeling of his age when he declared, "The condition of the free man is that he does not live for the benefit of another." With the exception of some military service, nonslave labour was simply not for sale.

Markets and a market system

The difference between a society with flourishing markets and a market-coordinated society is not, therefore, merely one of attitudes. Before a system orchestrated by the market can replace one built on obedience to communal or superior pressure, the social orders dependent on tradition and command must be replaced by a new order in which individuals are expected to fend for themselves and in which all are permitted, even encouraged, to improve their material condition. Individuals cannot have such aims, much less such "rights," until the unchallengeable authority of custom or hierarchical privilege has been swept away. A rearrangement of this magnitude entails wrenching dislocations of power and prerogative. A market society is not, consequently, merely a society coordinated by markets. It is, of necessity, a social order with a distinctive structure of laws and privileges.

It follows that a market society requires an organizing principle that, by definition, can no longer be the respect accorded to tradition or the obedience owed to a political elite. This principle becomes the generalized search for material gain. Such a condition of universal upward striving is unimaginable in a traditional society and could only be seen as a dangerous threat in a society built on established hierarchies of authority. But, for reasons that will be seen, it is magically accommodated by, and indeed constitutive of, the workings of a market system.

The process by which these institutional and attitudinal changes are brought about constitutes a grand theme—per-

haps the grand theme—of economic history from roughly the 5th to the 18th and even into the 19th century in Europe. In terms of political history the period was marked by the collapse of the Roman empire, the rise of feudalism, and the slow formation of national states. In social terms it featured the end of an order characterized by an imperial retinue at the top and massive slavery at the bottom, its replacement by gradations of feudal vassalage descending from lord to serf, and the eventual appearance of a bourgeois society with distinct classes of workers, landlords, and capitalists. From the economist's perspective it was marked by the breakdown of a coordinative mechanism of centralized command, the rise of the mixed pressures of tradition and local command characteristic of the feudal manor, and the gradual displacement of those pressures by the material penalties and rewards of an all-embracing market network. In this vast transformation, the rise of the market mechanism became crucial as the means by which the new social formation of capitalism assured its self-provisioning, but the mechanism itself rested on deeper-lying social, cultural, and political changes that created the capitalist order which it served.

To attempt to trace these lineages of capitalism would take one far beyond the confines of the present subject. Suffice it to remark that the emergence of the new order was first given expression in the 10th and 11th centuries when a rising mercantile "estate" began to bargain successfully for recognition and protection with the local lords and impecunious monarchs of the early Middle Ages. Not until the 16th and 17th centuries was there a "commercialization" of the aristocratic strata, many of whom fared poorly in an ever more money-oriented world, and who accordingly contracted marriages with merchant families whom they would not have received at home a generation or two earlier. Of greatest significance, however, was the transformation of the lower orders, a process that began in Elizabethan England but did not take place en masse until the 18th and even 19th centuries. As traditional lords became profit-minded landlords, peasants were forced off the land to become an agricultural proletariat in search of the best wages it could get because its traditional subsistence was no longer available. Thus the market network extended its disciplinary power over "free" labour—the resource that had always previously eluded its influence. A social order had been created in which markets could coordinate production and distribution in a manner never before possible.

THE EVOLUTION OF CAPITALISM

Emergence of mercantilism

From mercantilism to commercial capitalism. It is usual to describe the earliest stages of capitalism as mercantilism, the word denoting the central importance of the merchant overseas traders who rose to prominence in 17th- and 18th-century England, Germany, and the Low Countries. In numerous pamphlets these merchants defended the principle that their trading activities buttressed the interest of the sovereign power, even when, to the consternation of the court, this required sending "treasure" (bullion) abroad. As the pamphleteers explained, treasure used in this way became itself a commodity in foreign trade, in which, as the great merchant Thomas Mun wrote about 1630, "we must ever observe this rule; to sell more to strangers than we consume of theirs in value."

For all its trading mentality, mercantilism was only partially a market-coordinated system. Smith complained bitterly about the government monopolies that granted exclusive trading rights to groups such as the East India or the Turkey companies, and modern commentators have emphasized the degree to which mercantilist economies relied on regulated, not free, prices and wages. The economic society that Smith described in *The Wealth of Nations* in 1776 is much closer to modern society, although it differs in many respects, as shall be seen. This 18th-century stage is called "commercial capitalism," although it should be noted that the word "capitalism" itself does not actually appear in the pages of Smith's great book.

Smith's society is nonetheless recognizable as capitalist precisely because of the prominence of those elements that had been absent in its mercantilist form. For example, with few exceptions, the production and distribution of all goods and services were entrusted to market forces rather than to the rules and regulations that had abounded a century earlier. The level of wages was likewise mainly determined by the interplay of the supply of, and the demand for, labour, not by the rulings of local magistrates. Profits were exposed to competition rather than protected by government monopoly.

Perhaps of greater importance in perceiving Smith's world as capitalist, as well as market-oriented, is its clear division of society into an economic and a political realm. The role of government had been gradually narrowed until Smith could describe its duties as consisting of only three functions: (1) the provision of national defense, (2) the protection of each member of society from the injustice or oppression of any other, and (3) the erection and maintenance of those public works and public institutions (including education) that would not repay the expense of any private enterpriser, although they might "do much more than repay it" to society as a whole. And if the realm of government had been greatly delimited, that of commerce had been greatly expanded. The accumulation of capital had become clearly recognized as the driving engine of the system. The expansion of "capitals"—Smith's term for firms—was the motive power by which the market system was launched on its historic course.

Narrowed role of the state

Thus in *The Wealth of Nations* it was possible for the first time to describe quite precisely the dynamics as well as the coordinative processes of capitalism. The latter were entrusted to the market mechanism—which is to say, to the universal drive for material betterment, curbed and contained by the necessary condition of competition. Smith's great perception was that the combination of this drive and counterforce would direct productive activity toward those goods and services for which the public had the means and desire to pay, while forcing producers to satisfy those wants at prices that yielded no more than normal profits. Later economists would devote a great deal of attention to the question of whether competition in fact adequately constrains the workings of the acquisitive drive and whether a market system might not display cycles and crises unmentioned in *The Wealth of Nations.* These were questions unknown to Smith, because the institutions that would produce them, above all the development of large-scale industry, lay in the future. Given these historic realities, one can only admire Smith's perception of the market as a means of solving the economic problem.

Smith also saw that the competitive search for capital accumulation would impart a distinctive tendency to a society that harnessed its motive force. He pointed out that the most obvious way for a manufacturer to gain wealth was to expand his enterprise by hiring additional workers. As firms expanded their individual operations, manufacturers found that they could subdivide complex tasks into simpler ones and could then speed along these simpler tasks by providing their operatives with machinery. Thus the expansion of firms made possible an ever finer division of labour, and the finer division of labour, in turn, improved profits by lowering the costs of production, thereby encouraging the further enlargement of the firms. In this way the incentives of the market system gave rise to the augmentation of the wealth of the nation itself, endowing market society with its all-important historical momentum and at the same time making room for the upward striving of its members.

Capitalism and productivity

One final attribute of the emerging system must be noted. This is the tearing apart of the formerly seamless tapestry of social coordination. Under capitalism two realms of authority existed where there had formerly been only one—a realm of political governance for such purposes as war or law and order and a realm of economic governance over the processes of production and distribution. Each realm was largely shielded from the reach of the other. The capitalists who dominated the market system were not automatically entitled to governing power, and the members of government were not entrusted with decisions as to what goods should be produced or how social rewards should be distributed. This new dual structure brought with it two consequences of immense importance.

The first was a limitation of political power that proved of very great importance in establishing democratic forms of government. The second, closer to the present theme, was the need for a new kind of analysis intended to clarify the workings of this new semi-independent realm within the larger social order. Thus did the appearance of capitalism give rise to the discipline now called economics.

From commercial to industrial capitalism. Commercial capitalism proved to be only transitional. The succeeding form would be distinguished by the pervasive mechanization and industrialization of its productive processes, a change that would not only vastly alter the social and physical landscape but would also set into motion new dynamic tendencies for the system.

The transformative agency was already present in Smith's day, observable in a few coal mines where steam-driven engines invented by Thomas Newcomen pumped water out of the pits. The diffusion and penetration of such machinery-driven processes of production during the first quarter of the next century has been traditionally called "the" Industrial Revolution, although historians today stress the long germination of the revolution and the many phases through which it passed. There is no doubt, however, that a remarkable confluence of advances in agriculture, cotton spinning and weaving, iron manufacture, machine tool design, and the harnessing of mechanical power began profoundly to alter the character of capitalism in the last years of the 18th century and the first decades of the 19th.

The alterations did not affect the driving motive of the system or its reliance on market forces as its coordinative principles. Their effect was rather on the social complexion of the society that contained these new technologies and on the economic outcome of the processes of competition and capital accumulation. This aspect of industrialization was most immediately apparent in the advent of the factory as the archetypal locus of production. In Smith's time the individual enterprise was still small—the opening pages of *The Wealth of Nations* describe the effects of the division of labour in a 10-man pin factory—but by the early 19th century the increasing mechanization of labour, coupled with the application of water and steam power, had raised the size of the work force in an ordinary textile mill to several hundreds, by midcentury in the steel mills to several thousands, and by the end of the century in the railways to tens of thousands.

Labour under capitalism

The increase in the scale of employment brought a marked change in the character of employment itself. In Smith's day the social distance between employer and labourer was still sufficiently small that the very word "manufacturer" implied an occupation (a mechanic) as well as a capitalist-like position. By the time of the "dark satanic mills" of the 1830s, a great gulf had opened between the manufacturers, who were now a propertied business class, and the men, women, and children who tended their machines for 10- and 12-hour stints. It was from the spectacle of mill labour, described in unsparing detail by the inspectors authorized by the first Factory Act of 1802, that Marx drew much of the indignation that animated his analysis of capitalism. More important, it was from this same factory setting, and from the urban squalor that industrialization also brought, that capitalism derived much of the social consciousness—sometimes revolutionary, sometimes reformist—that was to play so large a part in its subsequent political life.

The degradation of the physical and social landscape was the aspect of industrialization that first attracted attention, but it was its slower-acting impact on economic growth that was ultimately to be judged its most significant effect. A single statistic may dramatize this process. Between 1788 and 1839 the output of pig iron in Britain rose from 68,000 to 1,347,000 tons. For the significance of these numbers to be grasped, they must be translated into the huge multiplication of iron pumps, iron machine tools, iron pipes, iron rails, and iron beams that this increase in pig iron production made possible, and this multiplication of iron implements must in turn be translated into the strength and speed that they lent to production itself. This was the means by which the first industrial revolution promoted economic growth, not immediately but with gathering momentum. Thirty years later this effect would be repeated with even more spectacular results when the Bessemer converter ushered in the age of steel rails, ships, machines, girders, wires, pipes, and containers.

The most important consequence of the industrialization of capitalism was therefore its powerful effect on enhancing what Marx called "the forces of production"—the source of what is now called standard of living. The Swiss economic demographer Paul Bairoch has calculated that gross national product per capita in the developed countries rose from $180 in the 1750s (in dollars of 1960 purchasing power) to $780 in the 1930s and then to $3,000 in the 1980s, whereas the per capita income of the less developed countries remained unchanged at about $180–$190 from 1750 to 1930 and thereafter rose only to $410 in 1980. The single most important explanation for this difference is that the first group of countries became industrialized and the second did not.

Industrialization and national wealth

A second major effect of the industrialization of the system was its increasing economic instability. Market systems are intrinsically susceptible to perturbations, because of mismatches and miscalculations in individual markets. Such disturbances bring relatively small effects in an economy of small enterprises, but they can have major repercussions as the scale of enterprises becomes larger. The difference can be likened to the contrast between a sand pile and a girdered structure: the sand pile absorbs blows without collapsing because of the adjustment of its many small particles, while a girdered structure can fail if a single beam buckles.

Not surprisingly, then, one side effect of industrialization was the effort to minimize or prevent such shocks by linking firms together into cartels or trusts or simply into giant integrated enterprises. Although these efforts dampened the repercussions of individual miscalculations, they were insufficient to guard against the effects of speculative panics or commercial convulsions. By the end of the 19th century, economic depressions had become a worrisome and recurrent problem, and the Great Depression of the 1930s rocked the entire capitalist world. During that debacle, the gross national product (GNP) in the United States fell by almost 50 percent from its peak to its trough; business investment fell by 94 percent, while unemployment rose from 3.2 percent of the civilian labour force to 24.9 percent. Of all the reasons that account for the extraordinary increase in instability from 1830 to 1930, none is more persuasive than the increase in scale from pin factories to giant enterprises.

From industrial to state capitalism. The problem of instability takes on further importance insofar as it is a principal cause of the next structural phase of the system. The new phase is often described as state capitalism because its outstanding feature is the enlargement in size and functions of the public realm. In 1929, for example, total U.S. government expenditures—federal, state, and local—came to less than 10 percent of the GNP; from the 1970s, they amounted to roughly one-third. This increase is observable in all major capitalist nations, many of which have reached considerably higher ratios of government disbursements to GNP than the United States.

At the same time, the function of government changed as decisively as its size. Already by the last quarter of the 19th century the emergence of great industrial trusts had provoked legislation in the United States (although not in Europe) to curb the monopolistic tendencies of industrialization. Apart from these antitrust laws and the regulation of a few industries of special public concern, however, the functions of the federal government were not significantly broadened from Smith's vision. Prior to the Great Depression, for example, the great bulk of federal outlays went for defense and international relations, for general administrative expense and interest on the debt, and for the post office.

The Great Depression radically altered this limited view of government in the United States, as it had earlier begun to widen it in Europe. The provision of old-age pensions, relief for the hungry and poor, and a dole for the unemployed were all policies inaugurated by the administration

Growth of government's role

of President Franklin D. Roosevelt, following in the footsteps of similar enlargements of government functions in Britain, France, and Germany. From the 1970s forward, such new kinds of federal activities—under the designation of social security, health, education, and welfare expenditures—grew to be 20 to 50 percent larger than the traditional categories of federal spending.

Thus, one very important element in the advent of a new stage of capitalism was the emergence of the public sector as a guarantor of public economic well-being, a function that would never have entered Smith's imagination. A second and equally important departure was the government's assumption of responsibility for the general course of economic conditions themselves. This was a change of policy orientation that also emerged from the challenge of the Great Depression. Once regarded as a matter beyond remedy, the general level of national income came to be seen by the end of the 1930s as the responsibility of government, although the measures taken to improve conditions were on the whole timid, often wrongheaded (such as highly protectionist trade policies), and only modestly successful. Nonetheless, the appearance in that decade of a new economic accountability for government constitutes in itself sufficient reason to describe capitalism today in terms that distinguish it from its industrial, but largely unguided, past.

There is little doubt that capitalism in the 21st century will undergo still further structural alterations. Technological advances are rapidly reducing to near insignificance the once formidable barriers and opportunities of economic geography. Among the startling consequences of this technological leveling of the world have been the displacement of the economic centre of the globe from the Atlantic to the Pacific and the threat of large displacements of high-tech manufacture from Europe and North America to low-wage regions of Southwest Asia, Latin America, and possibly Africa. Another change has been the unprecedented growth of international finance to the point at which the total value of transactions in foreign exchange is estimated to be at least 20 times that of all foreign movements of goods and services. This boundary-blind internationalization of finance, combined with the boundary-defying ability of large corporations to locate their operations in low-wage countries, poses a challenge to the traditional economic sovereignty of nations, a challenge arising from the new capabilities of capital itself.

Internationalization of finance

A third change again involves the international economy, this time through the creation of new institutions for the management of international economic trade. A number of capitalist nations have met the challenges of the fast-growing international economy by joining the energies of the private sector (including organized labour) with the financial and negotiating powers of the state. This "corporatist" approach, most clearly evident in the organization of the Japanese economy, may become a common structural characteristic of capitalism in the 21st century, not only in managing foreign trade and production but also in dealing with domestic problems such as inflation.

These still-emergent trends seem likely to exert their pressures toward further growth of the governmental guiding role within capitalism. It is not necessary, however, to venture risky predictions as to the future. Rather, it seems more useful to conclude with two generalizations. The first emphasizes that capitalism in all its variations continues to be distinguished from other economic systems by the priority accorded to the drive for wealth and the centrality of the competitive mechanism that channels this drive toward those ends that the market rewards. The second generalization is that this driving force and constraining mechanism appear to be compatible with a wide variety of institutional settings, including substantial variations in the relationships between the private and public sectors. It is to this very adaptability that capitalism appears to owe its continued vitality.

CENTRALLY PLANNED SYSTEMS

No survey of comparative economic systems would be complete without an account of centrally planned systems, the modern descendants of the command economies of the imperial past. In sharpest possible contrast to those earlier tributary arrangements, however, modern command societies have virtually all been organized in the name of socialism—that is, with the function of command officially administered on behalf of the broad masses of the population.

Socialist central planning needs to be differentiated from the idea of socialism itself. The latter draws on moral precepts of concern for the needy that can be discovered in the Judeo-Christian tradition and derives its general social orientation from Gerrard Winstanley's Diggers movement during the English Civil Wars in the mid-17th century: "The Earth," Winstanley wrote, "was made by Almighty God to be a Common Treasury of livelihood to the whole of mankind . . . without respect of persons."

Socialism as a means of orchestrating a modern industrial system did not receive explicit attention until the Russian Revolution in 1917. In his brochure *The State and Revolution,* written before he came to power, Lenin envisaged the task of coordinating a socialist economy as little more than delivering production to central collecting points from which it would be distributed according to need—an operation requiring no more than "the extraordinarily simple operations of watching, recording, and issuing receipts, within the reach of anybody who can read and who knows the first four rules of arithmetic." After the revolution, it soon became apparent that the problem was a great deal more difficult than that. The mobilization of manpower required the complex determination of appropriate amounts and levels of pay, and the mobilization of foodstuffs from the countryside posed the awkward question of the degree to which the "bourgeois" peasantry would have to be accommodated. As civil war raged in the country, these problems intensified until production fell to a catastrophic 14 percent of prewar levels. By the end of 1920 the system was at the verge of collapse.

Lenin's simplistic view

To forestall disaster, Lenin instituted the New Economic Policy (NEP), which amounted to a partial restoration of capitalism, especially in retail trade, small-scale production, and agriculture. Only the "commanding heights" of the economy remained in government hands. The NEP resuscitated the economy but opened a period of intense debate as to the use of market incentives versus moral suasion or more coercive techniques. The debate, which remained unresolved during Lenin's life, was brought to a conclusion at his death in 1924, when Joseph Stalin rose to power and rapidly forced the collectivization of the economy. Private agriculture was converted into collective farming with great cruelty and loss of life, all capitalist markets and private enterprises were quickly and ruthlessly eliminated, and the direction of economic life was consigned to a bureaucracy of ministries and planning agencies. By the 1930s a structure of centralized planning had been put into place that was to coordinate the Russian economy for the next half century.

Soviet planning. At the centre of the planning system was the Gosplan (*gos* means "committee"), the top economic planning agency of the Soviet state. Above the Gosplan were the political arms of the Soviet government, while below it were smaller planning agencies for the various Soviet republics. The Gosplan itself was staffed by economists and statisticians charged with drawing up what amounted to a blueprint for national economic activity, usually for a five- to seven-year period. This blueprint translated the major objectives determined by political decision (electrification targets, agricultural goals, transportation networks, and the like) into industry-specific requirements (outputs of generators, fertilizers, steel rails). These general requirements were then referred to ministries charged with the management of the industries in question, where the targets were further broken down into specific outputs (quantities, qualities, shapes, and sizes of steel plates, girders, rods, wires, and so forth) and where lower-level goals were fixed, such as budgets for firms, wage rates for different skill levels, or managerial bonuses.

Planning was not, therefore, entirely a one-way process. General objectives were indeed transmitted from the top down, but as each ministry and factory inspected its obligations, specific obstacles and difficulties were transmitted

from the bottom up. The final plan was thus a compromise between the political objectives of the Central Committee of the Communist Party and the nuts-and-bolts considerations of the echelons charged with its execution. This coordinative mechanism worked quite well when the larger objectives of the system called for a kind of crash planning that resembled a war economy. The Soviet economy achieved unprecedentedly rapid progress in its industrialization drive before World War II and in repairing the devastation that followed the war. Moreover, in areas where the political stakes were high, such as space technology, the planning system was able to concentrate skills and resources regardless of cost. Yet, charged with the orchestration of a civilian economy in normal peacetime conditions, the system of centralized planning failed seriously, for reasons that will be examined below.

Perestroika in Soviet planning

Because of its failures, a far-reaching reorganization of the system was set into motion in 1985 by Mikhail Gorbachev, under the banner of *perestroika* ("restructuring"). The extent of the restructuring can be judged by these proposed changes in the coordinative system: (1) the scope and penetration of planning were to be greatly curtailed and directed mainly at general economic goals, such as rates of growth, consumption or investment targets, or regional development; (2) planning done for factory enterprises was to give way to planning by factories themselves, guided by considerations of profit and loss; (3) factory managers were no longer to be bound by instructions with respect to the sources of their inputs and the destination of their outputs but were to be free to buy from and to sell to whomever they pleased; (4) managers were also to be free to hire and—more important—to fire workers, who formerly could not be easily discharged; and (5) many kinds of small private enterprises were to be encouraged, especially in farming and the retail trades.

This program obviously represented a dramatic retreat from the original idea of central planning. One cannot say, however, that it also represented a decisive turn from socialism to capitalism, for it was not clear to what extent the restructured planning system might embody other essential features of capitalism, such as private ownership of the means of production and the exclusion of political power from the normal operations of economic life. Nor was it known to what extent economic *perestroika* was to be accompanied by its political counterpart, *glasnost* ("openness"). Thus the degree of change in both the economic structure and the underlying political order remained indeterminate. The record of *perestroika* over the rest of the 1980s was disappointing. After an initial flush of enthusiasm, the task of abandoning the centralized planning system proved to be far more difficult than anticipated, to no small degree because the achievement of such a change would have necessitated the creation of a new structure of economic (managerial) power, independent of, and to some extent in continuous tension with, that of political power, much as under capitalism. Also, the operation of the centralized planning system, freed from some of the coercive pressures of the past but not yet infused with the energies of the market, rapidly deteriorated. By the end of the decade, the Soviet system was facing an economic breakdown more severe and far-reaching than the worst capitalist crisis of the 1930s. Not surprisingly, the unrest aroused ancient nationalist rivalries and ambitions.

As the Soviet central government gradually lost control over the economy at the republic and local levels, the system of central planning eroded without adequate free-market mechanisms to replace it. By 1990 the Soviet economy had slid into near-paralysis, and this condition foreshadowed the fall from power of the Soviet Communist Party and the breakup of the Soviet Union itself into a group of independent republics in 1991. Attempts to transform socialist systems into market economies have occurred in eastern and central Europe since 1989 and in the former Soviet Union since 1992. Ambitious privatization programs have been pursued in Poland, Hungary, Germany, the Czech Republic, and Russia. The same countries also have made the transition (with varying degrees of success) to democratic forms of governance.

Mixed economies. The socialist turn from planning toward the market provides a fitting initial conclusion to this overview of the typology of economic systems, for it is apparent that the three ideal types of tradition, command, and market have never been attained in wholly pure form. Perhaps the most undiluted of these modes in practice has been that of tradition, the great means of orchestration in pre-state economic life. But, even in tradition, a form of command can be seen in the expected obedience of community members to the sanctions of tradition. In the great command systems of the past, as has been seen, tradition supplied important stabilizing functions, and traces of market exchange served to connect these systems to others beyond their borders. The market system, as well, has never existed in wholly pure form. Market societies have always taken for granted that tradition would provide the foundation of trustworthiness and honesty without which a market-knit society would require an impossible degree of supervision, and no capitalist society has ever existed without a core of public economic undertakings, of which Smith's triad—defense, law and order, and nonprofitable public works—constitute the irreducible minimum.

Thus it is not surprising that the Soviet Union's efforts to find a more flexible amalgam of planning and market were anticipated by several decades of cautious experiment in some of the socialist countries of eastern Europe, especially Yugoslavia and Hungary, and by bold departures from central planning in China after 1979. All these economies existed in some degree of flux as their governments sought configurations best suited to their institutional legacies, political ideologies, and cultural traditions. All of them also encountered problems similar in kind, although not in degree, to those of the Soviet Union as they sought to escape the confines of highly centralized economic control.

Experiments in mixed economies

Something of this mixed system of coordination can also be seen in the less developed regions of the world. The panorama of these economies is a kind of museum of economic systems, with tradition-dominated tribal societies, absolute monarchies, and semifeudal societies side by side with military socialisms and sophisticated, but unevenly developed, capitalisms. To some extent this spectrum reflects the legacy of 19th-century imperialist capitalism, against whose cultural, as well as economic, hegemony all latecomers have had to struggle. Little can be ventured as to the outcome of this astonishing variety of economic structures. A few countries may follow the corporatist model of the Pacific Rim economies; others may emulate the social democratic states of western Europe; a few will pursue a *laissez faire* approach; yet others will seek whatever method—either market or planning—that might help them establish a viable place in the international arena. Unfortunately, many are likely to remain destitute for some time. In this fateful drama, considerations of culture and politics are likely to play a more determinative role than any choice of economic instrumentalities.

APPRAISING ECONOMIC SYSTEMS

The study of economic systems begins from a historical account of the three coordinative modes of production and distribution, but it leads toward normative appraisals or comparisons of the advantages and deficiencies of the social orders that principally depend on these modes. To survey, much less to probe, these problems for capitalism and socialism would require nothing less than a review of contemporary economics. The remainder of this article will therefore briefly discuss a few aspects of socialism and of capitalism that highlight some of the major normative issues of this historical overview.

The socialist alternative. The chief economic problem of socialism has been the efficient performance of the very task for which its planning apparatus exists, namely the effective coordination of production and distribution. Conservative critics have declared that a planned economy is impossible—*i.e.*, will inevitably become unmanageably chaotic—by virtue of the need for a planning agency to make the millions of dovetailing decisions necessary to bring into existence the gigantic catalog of goods and services of a modern society. Precisely such problems became manifest in the late 1980s in the Soviet Union.

The proposed remedy for this, as noted above, is the use

of market arrangements within socialism, under which managers are free to conduct the affairs of their enterprises according to the dictates of supply and demand rather than those of a central authority. The difficulty with this solution lies in its political rather than economic requirements. The acceptance of a market system entrusted with the coordination of the bulk of economic activity requires the tolerance of a sphere of private authority apart from that of public authority. A market mechanism may be compatible with a society of socialist principles, but it requires that the present forms of such a society be radically reorganized. The political difficulties of such a reorganization are twofold. One is the tensions that can be expected to exist between the private interests, and no doubt the public visions, of the managerial echelons and those of the political regime. The creation of a market is tantamount to the creation of a realm within the socialist order into which the political arm of government is not allowed to reach fully. This almost surely entails the creation and defense of various privileges, including contract and property, that resemble those of capitalism. The threat is thus the introduction of a capitalist virus within the socialist order, the mirror image of the socialist virus that is often perceived in capitalist societies as residing in their government realms.

A second political difficulty concerns the working class, not the managerial elites. The establishment of a market system as a major coordinator of economic activity necessarily introduces the use of unemployment as a disciplining force into a social order that uses commands to allocate employment and that does not permit workers to be hired or fired for strictly economic reasons. This use of unemployment is likely to exacerbate class tensions between workers and management. Socialist reformers envisage the overcoming of these tensions by increasing worker participation in the management of the enterprises in which they work. This has been attempted for some years on a limited scale in a few countries, but no great successes have been reported.

Problems of capitalism. Advocates and critics of capitalism agree that its distinctive contribution to history has been the encouragement of economic growth. Critics, however, cite three dysfunctions that reflect its market origins.

The unreliability of growth. The first of these problems is already familiar from the above survey of the stages of capitalist development. It is the instability that has characterized and plagued the system since the advent of industrialization. Because capitalist growth is driven by profit expectations, it fluctuates with the adventitious opening of technological or social opportunities for capital accumulation. As opportunities appear, capital rushes in to take advantage of them, bringing as a consequence the familiar attributes of a boom. Sooner or later, however, the rush subsides, as the demand for the new products or services becomes saturated, bringing a halt to investment, a shakeout in the main industries caught up in the previous boom, and the advent of recession. Hence economic growth comes at the price of a succession of market gluts as booms meet their inevitable end.

Capitalism's boom-and-bust cycle

This criticism did not receive its full exposition until the publication of Marx's *Das Kapital* in 1867. For Marx, the path of growth is not only unstable for the reasons just mentioned—Marx called such uncoordinated movements the "anarchy" of the market—but increasingly unstable. The reason for this is also familiar. It is the result of the industrialization process, which leads toward large-scale enterprises. As each saturation brings growth to a halt, a process of winnowing takes place in which the more successful firms are able to acquire the assets of the less successful. Thus the very dynamics of growth tend to concentrate capital into ever-larger firms. This leads to still more massive disruptions when the next boom ends, a process that terminates, according to Marx, only when the temper of the working class snaps and capitalism is replaced by socialism.

Marx's apocalyptic expectations have been largely replaced since the 1930s by the less violent but equally disquieting views of the English economist John Maynard Keynes, first set forth in his influential *The General Theory of Employment, Interest and Money* (1936). Keynes believed that the basic problem of capitalism is not so much its vulnerability to periodic saturations of investment as its likely failure to recover from them. He raised the possibility that a capitalist system could remain indefinitely in a condition of equilibrium despite high unemployment, a possibility not only entirely novel (even Marx believed that the system would recover its momentum after each crisis) but also one made plausible by the persisting unemployment of the 1930s. Keynes therefore raised the prospect that growth would end in stagnation, a condition for which the only remedy he saw was "a somewhat comprehensive socialization of investment."

The quality of growth. A second criticism with respect to market-driven growth focuses on the negative externalities—the adverse side effects—generated by a system of production that is held accountable only to the test of profitability. It is in the nature of a complex industrial society that the production processes of many commodities generate "bads" as well as "goods"—*e.g.*, toxic wastes or unhealthy working conditions, as well as useful outputs.

The externalities of economic activity

The catalog of such market-generated ills is very long. Smith himself warned that the division of labour, by routinizing work, would render workers "as stupid and ignorant as it is possible for a human creature to become," and Marx raised the spectre of alienation as the social price paid for the subordination of production to the imperatives of profit-making. A number of economists have warned that the introduction of technology designed to cut labour costs would create permanent unemployment. In modern times much attention has focused on the power of physical and chemical processes to surpass the carrying capacity of the environment—a concern made cogent by various types of environmental damage arising from excessive discharges of industrial effluents and products. Because these social and ecological challenges spring from the extraordinary powers of technology, they can be viewed as side effects of socialist as well as capitalist growth. But the argument can be made that market growth, by virtue of its overriding obedience to profit, is congenitally blind to such externalities.

Equity. A third criticism of capitalist growth concerns the fairness with which capitalism distributes its expanding wealth or with which it shares its recurrent hardships. This criticism takes on a specific and a general form.

The specific form focuses on disparities in income among layers of the population. At the end of the 20th century in the United States, for example, the lowest fifth of all families received only 3.6 percent of total income, whereas the topmost fifth received 49 percent. Significantly, this disparity results from the concentration of assets in the upper brackets. Also, it is the consequence of highly skewed patterns of corporate rewards that typically give, say, chief executive officers of large companies 50 to 100 times more income than those of ordinary office or factory employees. Income disparities, however, should be understood in perspective, because they stem from a number of causes. As observed in a report from the Federal Reserve Bank of Dallas, "By definition, there will always be a bottom 20 percent, but only in a strict caste society will it contain the same individuals and families year after year."

At a more general level, the criticism may be broadened to an indictment of the market principle itself as the regulator of incomes. The advocate of market-determined distribution declares that in such a society, with certain exceptions, people tend to be paid what they are worth—that is, their incomes reflect the value of their contribution to production. Thus market-based rewards lead to the efficiency of the productive system, thereby maximizing the total income available for distribution. This argument is countered at two levels. Marxist critics contend that labour under capitalism is systematically paid less than its value by virtue of the superior bargaining power of employers, so that the claim of efficiency masks an underlying condition of exploitation. Other critics question the criterion of efficiency itself, one that counts every dollar of input and output but pays no heed to the moral or social or aesthetic qualities of either and that excludes workers from expressing their own preferences as to the most appropriate decisions for their firms.

Corrective measures. Various measures have been taken by capitalist societies to meet these criticisms, although it must be recognized at the outset that a deep disagreement divides economists with respect to the appropriate corrective measures. A substantial body of conservative thinkers believe that many of the difficulties of the system spring not from its own workings but from well-meaning attempts to block or channel them. Thus, with respect to the problem of instability, supporters of the conservative view believe that capitalism, left as much as possible to itself, will naturally evidence the expansionary thrust that has marked its history and that whatever instabilities appear will tend quickly to correct themselves, provided that government plays a generally passive role. Conservatives do not deny that the system can give rise to qualitative or distributional ills, but they tend to believe that these are more than compensated for by its general expansive properties. Where specific problems remain, such as bad externalities or serious poverty, the conservative prescription often seeks to utilize the market system itself as the corrective agency—*e.g.*, controlling pollution by charging fees on the outflow of wastes rather than by banning the discharge of pollutants, or alleviating poverty through negative income taxes rather than by welfare payments.

The conservative defense

Opposing this view is a much more interventionist approach rooted in generally Keynesian and welfare-oriented policies. This view doubts the intrinsic momentum or reliability of capitalist growth and is therefore prepared to use active government means, both fiscal and monetary, to combat recession. It is also more skeptical as to the likelihood of improving the quality or the equity of society by market means and, although not opposing these, looks more favourably on direct regulatory intervention and on specific programs of assistance to disprivileged groups.

Despite this philosophical division of opinion, a fair degree of practical consensus has been reached on a number of issues. Although there are differences in policy style and determination from one nation to the next, all capitalist governments today take measures to overcome recession, whether by lowering taxes, by borrowing and spending, or by easing interest rates, and all pursue the opposite kinds of policies in inflationary times. It cannot be said that these policies have been unqualified successes, either in bringing about vigorous or steady growth or in ridding the system of its inflationary tendencies. Yet, imperfect though they are, these measures have been sufficient to prevent the development of socially destructive depressions or inflations. It is not the eradication but the limitation of instability that has been a signal achievement of all advanced capitalist countries since World War II. It should be noted, however, that these remedial measures have little or no international application. No institution exists to control credit for the world, comparable to the central banks that control it for individual nations; no global spending or taxing authority can speed up, or hold back, the pace of production for the industrial regions as a whole; no agency effectively oversees the availability of credit for the developing nations or the feasibility of the terms on which it may be extended. Thus, some critics of globalization contend that the internationalization of capitalism may exert destabilizing influences for which no policy corrective as yet exists.

Lack of international regulation

A broadly similar appraisal can be made with respect to the redress of specific threats that emerge as by-products from the market system. The issue is largely one of scale. Specific "bads" can often be redressed by market incentives to alter behaviour (paying a fee for returning used bottles) or, when the negative externality is more serious, by outright prohibition (bans on child labour or on dangerous chemical fertilizers). The problem becomes less amenable to control, however, when the market generates externalities of large proportions, such as traffic congestion in cities. The difficulty here is that the correction of such externalities requires the support and cooperation of the public and thereby crosses the line from the economic into the political arena, often making redress more difficult to obtain. On a still larger scale, the remedy for externalities may require international agreements, and these often raise conflicts of interest between the nation generating the ill effects as a by-product of its own production and those suffering from the effects.

A number of remedies have been applied against the distributional problems of capitalism. No advanced capitalist country today allows the market to distribute incomes without supplementing or altering the resulting pattern of rewards through taxes, subsidies, welfare systems, or entitlement payments such as old-age pensions and health benefits. In the United States these transfer payments, as they are called, amount to some 10 percent of total consumer income; in a number of European nations they come to considerably more. The result has been to lessen considerably the incidence of officially measured poverty. Yet these examples of successful government corrective action do not go unchallenged by those economists who are concerned that some of the "cures" applied to social problems may be worse than the "disease." Markets may fail, in other words, but so might governments.

Economic systems may lose some of the decisive differences that have marked them in the past, suggesting instead a continuum on which elements of both market and planning coexist in different proportions. Societies along such a continuum may continue to designate themselves as capitalist and socialist, but they are likely to reveal as many common aspects in the solutions to their economic problems as they may still display important differences.

BIBLIOGRAPHY

General texts: Historical analysis is presented in ROBERT L. HEILBRONER, *The Making of Economic Society*, 8th ed. (1989). An excellent presentation along more functional lines is FREDERIC L. PRYOR, *A Guidebook to the Comparative Study of Economic Systems* (1985). MORRIS BORNSTEIN (ed.), *Comparative Economic Systems: Models and Cases*, 6th ed. (1979), a book of readings, is also recommended.

Socialism: A history of the debate over the economic feasibility of socialism is available in DON LAVOIE, *Rivalry and Central Planning* (1985). A comprehensive reference collection is PETER J. BOETTKE (compiler), *Socialism and the Market: The Socialist Calculation Debate Revisited*, 9 vol. (2000). Other theoretical and historical works include ALEC NOVE, *The Economics of Feasible Socialism* (1983); BRANKO HORVAT, *The Political Economy of Socialism: A Marxist Social Theory* (1982); DAVID L. PRYCHITKO and JAROSLAV VANEK (eds.), *Producer Cooperatives and Labor-Managed Systems*, 2 vol. (1996); and JÁNUS KORNAI, *The Socialist System* (1992). Discussions regarding China, eastern Europe, and the former Soviet Union are in ANDREI SHLEIFER and DANIEL TREISMAN, *Without a Map: Political Tactics and Economic Reform in Russia* (2000); JEFFREY SACHS, *Poland's Jump: The Socialist Calculation Debate Reconsidered to the Market Economy* (1993); and BARRY NAUGHTON, *Growing Out of the Plan: Chinese Economic Reform, 1978–1993* (1995).

The Soviet experience: The classic work on the economic history of the Soviet Union is ALEC NOVE, *An Economic History of the U.S.S.R., 1917–1991*, 3rd ed. (1992). A political history of the Soviet Union is MARTIN MALIA, *The Soviet Tragedy: A History of Socialism in Russia, 1917–1997* (1994, reissued 1996). PETER J. BOETTKE, *Why Perestroika Failed: The Politics and Economics of Socialist Transformation* (1993), discusses systemic problems.

Capitalism: For broad treatments of capitalism, see ADAM SMITH, *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776); and KARL MARX, *Das Kapital*, (vol. 1, 1867); and *Capital: A Critical Analysis of Capitalist Production*, vol. 1 trans. by SAMUEL MOORE and EDWARD AVELING (1886); both works are available in many later editions. ROBERT L. HEILBRONER, *The Nature and Logic of Capitalism* (1985), treats the social formation of capitalism. FERNAND BRAUDEL, *Civilization and Capitalism, 15th–18th Century*, 3 vol. (1982–84; originally published in French, 1979), is a wide-ranging overview. NATHAN ROSENBERG and L.E. BIRDZELL, JR., *How the West Grew Rich: The Economic Transformation of the Industrial World* (1986, reissued 1999), discusses the Industrial Revolution and the rise of capitalism. JOHN KENNETH GALBRAITH, *The New Industrial State*, 4th ed. (1985), is a modern classic. MILTON FRIEDMAN, *Capitalism and Freedom* (1962) and *Free to Choose* (1980), treats economics and public policy from a market-oriented perspective. On the Japanese system, YUTAKA KOSAI and YOSHITARO OGINO, *The Contemporary Japanese Economy*, trans. from Japanese (1984), is useful but technical. (R.L.He./P.J.B.)

Economic Theory

Economic theory is the name commonly given to the more general and abstract parts of economics, the principles. These parts are no less practical than concrete-descriptive or applied economics but are less directly related to immediate problems. The mechanics of price relations or of markets afford a general explanation of the organization of production and distribution insofar as this is actually worked out and controlled through competitive buying and selling—which would largely be true even in a planned or socialistic economy that stopped short of complete military regimentation. This branch of the study bears somewhat the same relation to economic politics that pure physics bears to the engineering sciences. Hence the problems of value and distribution have continued to hold their place among the central concerns of economists. However, there has been a notable—one might say a revolutionary—change in the general character of the analysis. The older classical economists centred their attention on the long-run relations between value and costs and were generally content to dispose of short-run variations of price by merely invoking the formula of supply and demand. This was used without careful analysis of the short-run situation, particularly of the role of demand. Work directed toward filling in this gap had important effects in changing the whole conceptual picture. Enlarged theories of production, distribution, consumption, business fluctuations, and other economic elements have been introduced and continually reconsidered from a variety of viewpoints.

The article is divided into the following sections:

Utility and value

Value theory and prices

One purpose of value theory in economics is to explain how the prices of goods and services are determined. This is only a step, however, in the analysis of a deeper problem. The modern industrial economy is characterized by a high degree of interdependence of its parts. The supplier of components or raw materials, for example, must deliver the desired quantities of his products at the right moment and in the desired specifications. In economies such as those of western Europe, North America, and Japan, the coordination of these activities is done through the price system. The relative prices of the various inputs (*e.g.*, labour, materials, machinery) tend to determine the proportions in which they will be used. Prices also affect the relative outputs of the various final products, and they determine who will consume them. Value theory, therefore, studies the structure of these decisions, analyzes the influence of prices, and examines the efficiency of the resulting allocation of resources. Value theory is also applied by business firms and government agencies in their decisions that relate to pricing and the allocation of resources.

THEORIES OF VALUE

Cost-of-production analysis. Modern value theory began with Adam Smith (1776), David Ricardo (1817), and a number of other writers, who are generally lumped together as the classical school. These writers sought to explain pricing primarily on the basis of cost of production. That is, if commodity A costs twice as much to produce as commodity B, the price of A will be pushed toward a level twice as high as that of B. If this were not the case—

if, for example, A sold for three times the price of B—then the greater profitability of investment in A would cause its production to increase and drive down its price, while the production of B would decline, thus raising its price. Prices would finally be driven to the 2:1 ratio of the costs of production.

The classical economists were well aware of the oversimplification in this explanation, but, as with most theoretical analysis, its strength lay in the amount it was able to explain with a very simple model. (It is highly misleading to interpret the classical analysis literally, as a picture of its authors' views of the complex world of reality.) It was soon recognized, however, that the cost-of-production analysis considered only part of the relevant problem. Since cost depends on the quantity produced (*e.g.*, costs per unit may decline as production of an item increases), the analysis must take into account the demand for the product. The analysis of demand was made possible by the theory of utility, developed by H.H. Gossen in Germany (1854), Karl Menger in Austria (1871), Léon Walras in France (1874–77), and W.S. Jevons in England (1871).

The role of utility analysis in value theory will be discussed later. It need only be added at this point that modern value theory, following the lead of the English economist Alfred Marshall (*Principles of Economics*, 8th ed., 1920), considers prices to be determined simultaneously by cost and demand considerations. The analysis also recognizes the complex interdependencies in the system, with demands and supplies of various commodities affecting one another.

The concept of alternative uses

Resource limitations and allocation. The fact that goods have value can be ascribed ultimately to the limitations in the world's material endowment. Man does not have all the arable land, petroleum, or platinum that he would like; their use must be rationed. That is why goods have prices; if they were available in unlimited supply they would be free. Price usually serves as the rationing device whereby their use is kept down to the available supply.

Resources can be said to be scarce in both an absolute and in a relative sense: the surface of the Earth is finite, imposing absolute scarcity; but the scarcity that concerns economists is the relative scarcity of resources in different uses. Materials used for one purpose cannot at the same time be used for other purposes; if the quantity of an input is limited, the increased use of it in one manufacturing process must cause it to become scarcer in other uses.

The cost of a product in terms of money may not measure its true cost to society. The true cost of, say, the construction of a supersonic jet is the value of the schools and refrigerators that will never be built as a result. Every act of production uses up some of society's available resources; it means the foregoing of an opportunity to produce something else. In deciding how to use resources most effectively to satisfy the wants of the community, this opportunity cost must ultimately be taken into account.

In a market economy the relationship between the price of a good and the quantity supplied depends on the cost of making it, and that cost, ultimately, is the cost of *not* making other goods. The market mechanism enforces this relationship. In the first instance, the cost of, say, a pair of shoes is the price of the leather, the labour, the fuel, and other elements used up in producing them. But the price of these inputs, in turn, depends on what they can produce elsewhere—if the handbags that can be produced with the leather are valued very highly by consumers, the price of leather will be bid up correspondingly.

THEORIES OF UTILITY

There are two sides to the analysis of price and value: the supply side and the demand side. If cost can be said to underlie the supply relationship that determines price, the demand side must be taken to reflect consumer tastes and preferences. "Utility" is a concept that has been used to describe these tastes. As already indicated, the cost-of-production analysis of value given above is incomplete, because cost itself depends on the quantity produced. The cost analysis, moreover, applies only to commodities the production of which can be expanded and contracted. The price of a first-folio Shakespeare has no relation to cost of production; it must depend in some sense on its utility to purchasers as it affects their bids.

Marginal utility. The classical economists suggested that this leads to a paradox. They argued that utility could not explain the relative price of fine jade and bread, because the latter was for many consumers essential to life, and hence its utility must surely be greater than that of jade. Yet the price of bread is far lower than that of jade. The theory of marginal utility that flowered toward the end of the 19th century supplied the key to the paradox and provided the basis for today's analysis of demand. Marginal utility was defined as the value to the consumer of an additional unit of some commodity. If, for example, the consumer is offered a choice between 22 and 23 slices of bread for his family, marginal utility measures how much more valuable 23 slices are than 22. It is clear that the magnitude of the marginal utility varies with the magnitude of, say, the smaller of the alternatives. That is, for a family of four, the difference between seven and eight slices of bread per day can be substantial, if the family will still be hungry in either case. But the difference in value between 31 and 32 slices may be negligible, if 31 slices offer enough for everyone to fill his stomach, a 32nd slice may be worth very little. Moreover, the difference in value between 122 and 123 slices may be negative—a 123rd slice may just add to the family's disposal problem. These observations lead directly to the plausible notion that marginal utility in some sense diminishes with the base from which one starts the calculation. With only seven or eight slices the marginal utility (incremental value) of an eighth slice is high. With 31 or 32 slices it is lower, and so on. The less scarce a commodity, the lower is its marginal utility, because its possessor in any case will have enough to satisfy his most pressing uses for it, and an increment in his holdings will only permit him to satisfy, in addition, desires of lower priority.

Marginal utility and price

The consumer will be motivated to adjust his purchases so that the price of each and every good will be approximately equal to its marginal utility (that is, to the amount of money he is willing to pay for an additional unit). If the price of an item is P dollars, for example, and the consumer is considering buying, say, 10 units, at which point the marginal utility of the good to him is M (which is greater than P), the consumer will be better off if he purchases 11 rather than 10 units, since the additional unit costs him P dollars. He will keep revising his purchase plans upward until he reaches the point where the marginal utility of the item falls to P dollars. In sum, the consumer's self-interest will lead him (without conscious calculation) to purchase an amount such that the marginal utility is as close as possible to market price. So long as the consumer selects a bundle of purchases that gives him the most benefit (pleasure, utility) for his money, he must end up with quantities such that the marginal utility of each commodity in the bundle is approximately equal to its price.

It now becomes easy to explain the paradox underlying the relationship between the prices of jade and bread. Because a piece of fine jade is scarce, its marginal utility is high, and consumers are willing to pay comparatively high prices for it. The explanation is perfectly consistent with a utility analysis of demand, so long as one relates price to the marginal utility of the item rather than to its total utility. A family's bread may be very valuable to it, but, if it has enough, the marginal utility of the bread will be small, and this will be reflected in its low price.

The relationship between price and marginal utility is important not because it explains issues like the jade–bread paradox but because it enables one to analyze the relationship between prices and quantities demanded. It also, as a practical matter, permits one to judge how well any portion of the price mechanism is working as a device to secure the efficient satisfaction of the wants of the public, within the limits set by available resources. The conclusion that at any price the consumer will purchase the quantity at which marginal utility is equal to price makes it possible to draw a demand curve showing—to a reasonable degree of approximation—how the amount demanded will vary with price. A curve based on the

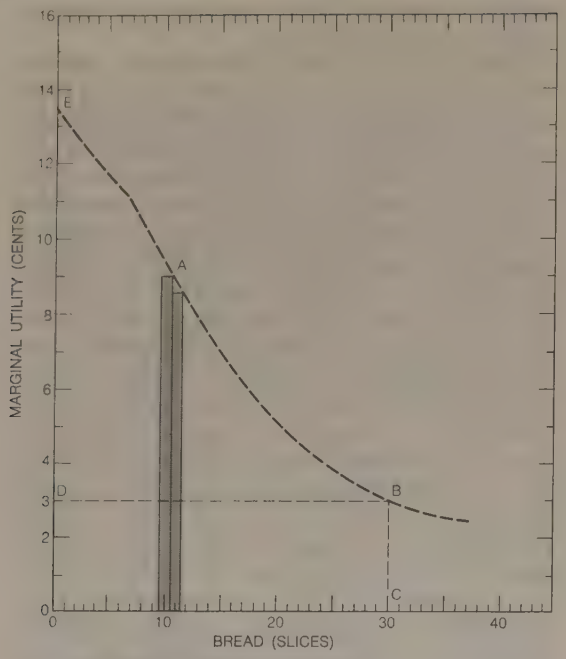

Figure 1: Relationship between marginal utility and quantity (see text).

previous example of bread consumption is given in Figure 1. This shows that if the family gets 10 slices per day the marginal utility of bread will be nine cents (point A). One may reverse the question and ask how much the family would purchase at any particular price, say three cents. The graph indicates that at this price the quantity would be 30 slices, because only at that quantity is marginal utility equal to the three-cent price (point B). Thus the curve in Figure 1, to a reasonable degree of approximation, may be able to do double duty: it may serve as a marginal-utility curve relating marginal utility to quantity and, at the same time, as a demand curve relating quantity demanded to price.

Consumers' surplus. Figure 1 leads to an important conclusion about the consumer's gains from his purchases. The diagram shows that the difference between 10 and 11 slices of bread is worth nine cents to the consumer (marginal utility = nine cents). Similarly, a 12th slice of bread is worth eight cents (see the shaded bars). Thus, the two slices of bread together are worth 17 cents, the area of the two rectangles together. Suppose the price of bread is actually three cents, and the consumer, therefore, purchases 30 slices per day. The total value of his purchases to him is the sum of the areas of all such rectangles for each of the 30 slices; *i.e.*, it is (approximately) equal to all of the area under the demand curve; that is, the area defined by the points 0CBE. The amount the consumer pays, however, is less than this area. His total expenditure is given by the area of rectangle 0CBD—90 cents. The difference between these two areas, the quasi-triangular area DBE, represents how much more the consumer would be willing to spend on the bread over and above the 90 cents he actually pays for it, if he were forced to do so. It represents the absolute maximum that could be extracted from the consumer for the bread by an unscrupulous merchant who had cornered the market. Since, normally, the consumer only pays quantity 0CBD, the area DBE is a net gain derived by the consumer from the transaction. It is called consumers' surplus. Virtually every purchase yields such a surplus to the buyer.

The concept of consumers' surplus is important for public policy, because it offers at least a crude measure of the public benefits of various types of economic activity. In deciding whether a government agency should build a dam, for example, one may estimate the consumers' surplus from the electricity the dam would generate and seek to compare it with the surplus that could be yielded by alternative uses of the resources needed to construct and operate the dam.

Consumers' preferences

Utility measurement and ordinal utility. As originally conceived, utility was taken to be a subjective measure of strength of feeling. An item that might be described as worth "40 utils" was to be interpreted to yield "twice as much pleasure" as one valued at 20 utils. It was not long before the usefulness of this concept was questioned. It was criticized for its subjectivity and the difficulty (if not impossibility) of quantifying it. An alternative line of analysis developed that was able to accomplish most of the same purposes but without as many assumptions. First introduced by the economists F.Y. Edgeworth in England (1881) and Vilfredo Pareto in Italy (1896–97), it was brought to fruition by Eugen Slutsky in Russia (1915) and J.R. Hicks and R.D.G. Allen in Great Britain (1934). The idea was that to analyze consumer choice between, say, two bundles of commodities, A and B, given their costs, one need know only that one is preferred to another. This may at first seem a trivial observation, but it is not as simple as it sounds.

Indifference analysis

In the following discussion, it is assumed for simplicity that there are only two commodities in the world. Figure 2 is a graph in which the axes measure the quantities of two commodities, X and Y. Thus, point A represents a bundle composed of seven units of commodity X and five units of commodity Y. The assumption is made that the consumer prefers to own more of either or both commodities. That means he must prefer bundle C to bundle A, because C lies directly to the right of A and hence contains more of X and no less of Y. Similarly, B must be preferred to A. But one cannot say, in general, whether

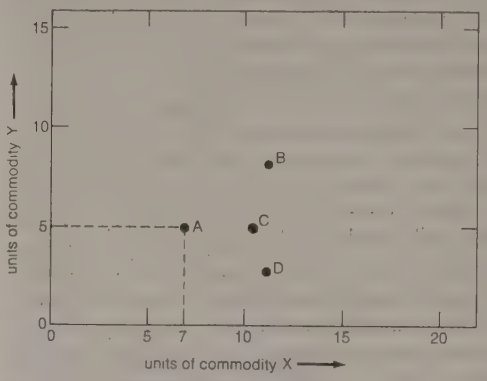

Figure 2: Commodities X and Y (see text).

A is preferred to D or vice versa, since one offers more of X and the other more of Y.

The consumer may in fact not care whether he receives A or D—that is, he may be indifferent (see Figure 3). Assuming that there is some continuity in his preferences, there will be a locus connecting A and D, any point on which (E or A or D) represents bundles of commodities of equal interest to this consumer. This locus (I–I′ in Figure 3) is called an indifference curve. It represents the consu-

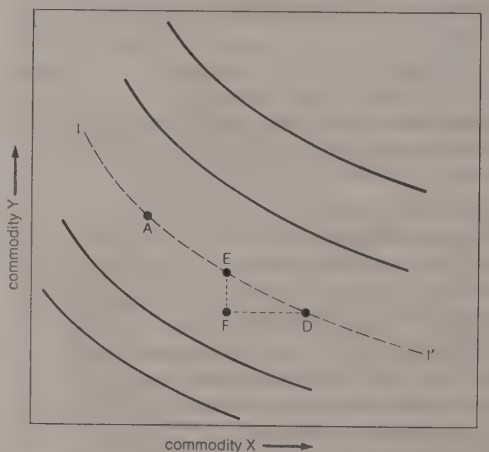

Figure 3: Indifference curves (see text).

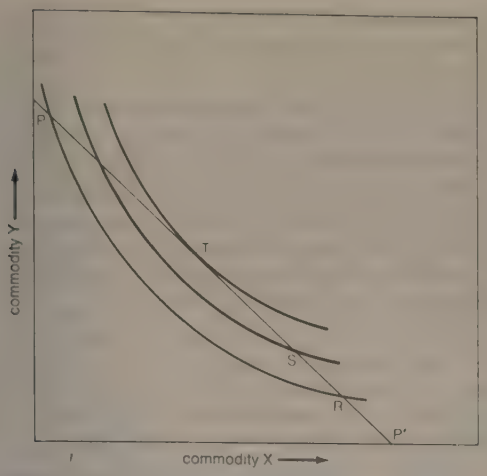

Figure 4: Indifference curves and a price line (see text).

mer's subjective trade off between the two commodities—how much more of one he will have to get to make up for the loss of a given amount of another. That is, one may treat the choice between bundle D and bundle E as involving the comparison of the gain of quantity FD of X with the loss of FE of Y. If the consumer is indifferent between D and E, the gain and loss just offset one another; hence, they indicate the proportion in which he is willing to exchange the two commodities. In mathematical terms, FE divided by FD represents the average slope of the indifference curve over arc ED; it is called the marginal rate of substitution between X and Y.

Figure 3 also contains other indifference curves, some representing combinations preferred to A (curves lying above and to the right of A) and some representing combinations to which A is preferred. These are like contour lines on a map, each such line being a locus of combinations that the consumer considers equally desirable. Conceptually, through every point in the diagram there is an indifference curve. Figure 3, with its family of indifference curves, is called an indifference map. This map obviously does no more than rank the available possibilities; it indicates whether one point is preferred to another but not by how much it is preferred.

It is easy to show that at any point such as E the slope of the indifference curve, roughly FE divided by ED, equals the ratio of the marginal utility of X to the marginal utility of Y for the corresponding quantities. For in moving from E to D the consumer gives up FE of Y, a loss valued, by definition, at approximately FE multiplied by the marginal utility of Y, and he gains FD of X, a gain worth FD multiplied by the marginal utility of X. Relative marginal utilities can be measured in this way because their ratio does not measure subjective quantities—rather, it represents a rate of exchange of two commodities. The marginal utility of X measured in money terms tells one how much of the commodity used as money the consumer is willing to give for more of the commodity X but not what psychic pleasure the consumer gains.

PRICES AND INCOMES

Indifference curves and the price line

One other type of information is needed to complete the analysis of consumer choice: the prices of X and Y and the amount the consumer has available to spend. In what follows, it will be assumed that the consumer spends all his money on the available commodities (savings bonds being among the commodities). If P_X and P_Y are the prices of commodities X and Y, respectively, and M represents the amount of money available for spending, the condition that all of the money is spent yields the equation

$$P_X X + P_Y Y = M \qquad (1)$$

or, solving for Y in terms of X,

$$Y = -\frac{P_X}{P_Y} X + \frac{M}{P_Y}. \qquad (2)$$

This is obviously the equation of a straight line with slope $-\frac{P_X}{P_Y}$ and with y-intercept $\frac{M}{P_Y}$. The line, called the budget line, or price line, represents all the combinations of X and Y that the consumer can afford to buy with income M at the given prices.

Equilibrium of the consumer. Figure 4 combines this price line and the indifference curves, permitting direct analysis of the consumer purchase decision. Line PP′ is the price line corresponding to equation (2) above. Any point R on that line represents a combination of X and Y that a given consumer can afford to purchase; however, R is not an optimal choice. This can be seen by comparing R with S on the same price line. Since S lies on a higher indifference curve than R, the former is the preferred position, and, since S costs no more than R (they are on the same price line, so each costs M dollars), S gives the consumer more for his money. It is at T, however, the point of tangency between the price line and an indifference curve, that the consumer reaches his highest indifference curve; this is, therefore, the optimal point for him, given his pattern of tastes as shown by the shapes of his indifference curves. This is the solution of the choice problem—it explains, in principle, the consumer's purchase decision on the basis of his given preferences, with no assumptions as to degrees of measurable utility.

The tangency at the solution point has a significant interpretation. It was noted above that the slope of the indifference curve is the ratio of the marginal utilities of the two commodities. It follows that, at the optimal point T, a dollar of expenditure must offer the same utility whether spent on X or on Y. If this is not so—as at point R in Figure 4, where the consumer gets more for his money by spending a dollar on Y rather than on X—it will pay him to reallocate his expenditures between the two commodities accordingly, moving toward S from R.

Changes in prices and incomes. The diagram becomes more illuminating when one investigates how the consumer's decision is affected by a change in his income or in the price of a commodity. Equation (2) indicates that a change in income, M, does not affect the slope of the price line, only its intercept. Thus, as the person's income increases, the price line undergoes a sequence of parallel shifts (Figure 5). For each such line there will be a point of tangency, T, with an indifference curve, showing the consumer's optimal bundle of purchases with the corresponding income. The locus of these points (T_1, T_2, T_3 . . .) may be called the income–consumption curve; it shows how the consumer's purchases vary with his income. Normally the curve will have a positive slope, as EE′ does in Figure 5A, meaning that as a person grows wealthier he will buy more of each commodity. But the slope can be negative for some stretches (GG′ in Figure 5B). In that case, X is said to be an inferior good of which the consumer buys less as his income rises.

Income–consumption curve

The diagram can also be used to show what happens as the price of X varies. From equation (2) it can be seen that the Y-intercept is not affected by an increase in the price of X but that the slope of the price line grows. Thus, as P_X rises, the price line shifts from PP′ to PR′ in Figure 6. This means that, as P_X rises, M dollars will buy as much of good Y as before (the position of point P at which all

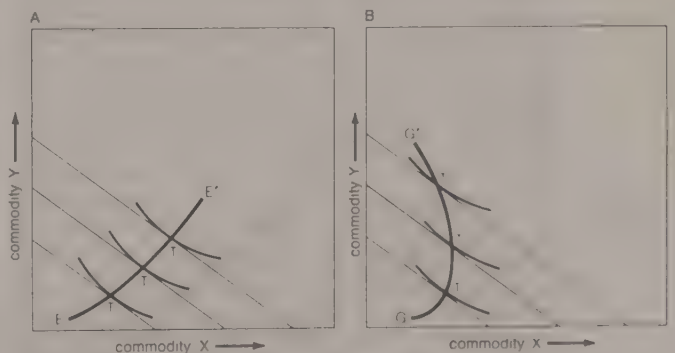

Figure 5: (A) Positive and (B) negative income–consumption curves (see text).

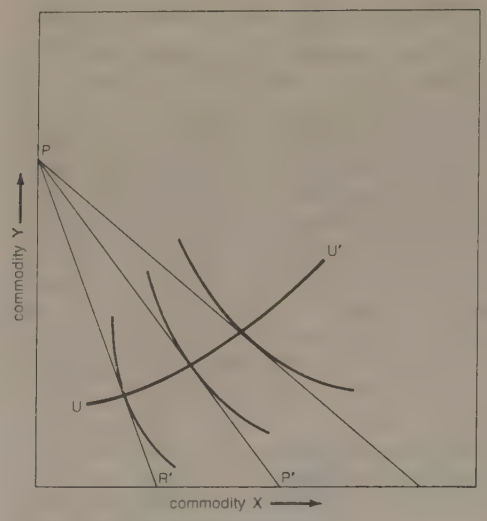

Figure 6: Price–consumption curve (see text).

M dollars are spent on commodity Y does not change), but that M dollars will now buy less of good X, so that the position of point P′ must move toward the left. Once again, by following the points of tangency between indifference curves and the price lines for various values of P_X, one contains a locus UU′, the price–consumption curve, showing how the consumer's purchases vary with P_X.

Income and substitution effects

It is useful to divide the effects of the price change conceptually into two parts. An increase in the price of X obviously affects the relative cost of X and Y. But it also decreases the consumer's overall purchasing power. The effect on purchases of this reduction of purchasing power is called the income effect of the price change. Its effect via the relative price change is called the substitution effect. The division can be carried out graphically as follows: let the price of X increase so that the price line in Figure 7 moves from PP′ to PR′, and assume an imaginary intermediate price line, LL′, with the slope of PR′ but tangent to the indifference curve that was attained with the old price line PP′. The imaginary price line has the following properties: (1) it involves the same real income as PP′ (tangency points T and S are the same indifference curve), and (2) it involves the same relative prices as the new price line since their slopes are the same. The rise in price has, in the figure, caused the demand for X to fall from C to A (the quantities of X corresponding to tangency points T and U). It has been possible to divide the total effect, CA, into two parts, the income effect, BA, and the substitution effect, CB. This breakdown is important, because a number of interesting and important theorems can be proved about the substitution effect. Two of these theorems will illustrate the point.

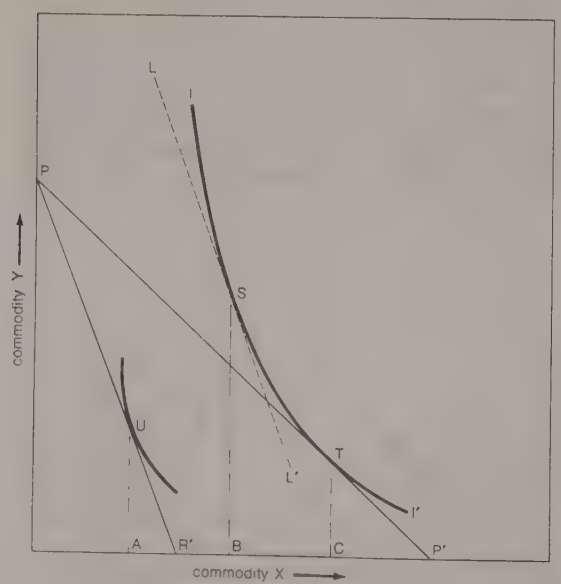

Figure 7: Income effect and substitution effect (see text).

Under the normal assumptions of demand theory it can be proved that a rise in the price of X must, via the substitution effect, work to reduce the demand for X; the second theorem states the surprising result that, considering only substitution effects, a dollar rise in the price of X must change the demand for Y by precisely the same amount as a dollar rise in the price of Y changes the demand for X. Similar relationships have been shown to hold when there are more than two commodities involved.

(W.J.B.)

Price

The price system, as it exists in western Europe and the Americas, is a means of organizing economic activity. It does this primarily by coordinating the decisions of consumers, producers, and owners of productive resources. Millions of economic agents who have no direct communication with each other are led by the price system to supply each other's wants. In a modern economy the price system enables a consumer to buy a product he has never previously purchased, produced by a firm of whose existence he is unaware, which is operating with funds partially obtained from his own savings.

Price as consensus value

Prices are an expression of the consensus on the values of different things, and every society that permits exchanges among men has prices. Because prices are expressed in terms of a widely acceptable commodity, they permit a ready comparison of the comparative values of various commodities—if shoes are $15 per pair and bread 30 cents per loaf, a pair of shoes is worth 50 loaves of bread. The price of anything is its value in exchange for a commodity of wide acceptability (money): the price of an automobile may be some 50 ounces of gold or 25 pieces of paper bearing the picture of an eminent statesman.

A system of prices exists because individual prices are related to each other. If, for example, copper rods cost 40 cents a pound and the process of drawing a rod into wire costs 25 cents a pound, then, if the price of wire exceeds 65 cents, it will be profitable to produce wire; and if the price of wire falls below 65 cents, it will be ruinous to produce wire. Competition, therefore, will hold the price of wire about 25 cents per pound above that of rods. A variety of such economic forces ties the entire structure of prices together.

The system of prices can be arranged to reward or penalize any kind of activity. Society discourages the production of electric shoestring-tying machines by the simple expedient of making such a machine's attainable selling price less than the prices of the resources necessary to produce it. Society stimulates people of large athletic promise to learn golf (rather than polo or cricket) by the immense prizes (= prices) that are given to tournament winners. The air in many cities is dirty because no one is charged a price for dirtying it and no one can pay a price for having it cleaned.

THE BASIC FUNCTIONS OF ECONOMIC SYSTEMS

Every economic system has three functions. In a decentralized (usually private enterprise) economic system, the price mechanism is the instrument by which these functions are performed.

One function is to determine what is to be produced and in what quantity. Even a primitive economy must choose between food and shelter, weapons and tools, priests and hunters. In a modern economy the potential variety of goods and services that may be produced is immense. Consider simply the 10,000 new book titles that are published each year or the hundreds of colours of paint or the thousands of styles of clothing that are produced—each of these actual collections being much smaller than modern technology permits.

A price system weighs the desires of consumers in terms of the prices they are willing to pay for various quantities of each commodity or service. The payment of $1,000 for

the services of a skilled surgeon (a price much influenced by the number of surgeons) reflects the great importance of his services to the buyer-patient, whereas the offer of 75 cents for a month's use of an additional telephone outlet reflects the minor convenience it provides. Of course the offers of consumers are influenced by their wealth as well as their desires, but for any one consumer relative desires are proportional to price offers.

Universal laws are most uncommon in social life. Economists nonetheless place immense confidence in the proposition that the consumer will buy less of any commodity when its price rises. This *law of demand* is by no means a necessary fact of life; rather it is an empirical rule to which there are no known, reliable exceptions. Bread, caviar, education, narcotics—a man will buy more of each when its price falls. These demand prices are the guides to producers that in effect tell them which commodities to produce and in what quantities.

The second function an economy must perform is to decide how the desired goods are to be produced. There is more than one way not only to skin a cat but also to grow wheat, train lawyers, refine petroleum, and transport baggage. The efficient production of goods requires that certain obvious rules be followed: no resource should be used in producing one thing when it could be producing something more valuable elsewhere; and each product should be made with the smallest possible amount of resources.

Allocation of resources

A functioning price system steers resources into their most important use by appealing to the desires of their owners for large incomes. For example, the person capable of being a surgeon is drawn to this occupation from, say, that of a high school teacher by the promise of annual earnings (= price of labour) much more than those of the high school teacher. Capital is drawn from a faltering trade to a booming new industry in which it receives a higher return.

This same price system seeks to achieve production efficiency through the sanction of competition. If one firm, for instance, can produce shoes with fewer resources than its rivals, it will make larger profits; so it is stirred to discover more efficient combinations of inputs and location of plant, to devise wage systems to stimulate its workers, to use computers to reduce inventories, and so forth without end.

The third function of an economy is to determine who gets the product. Family A gets $5,000 worth of goods this year, family B five times as much—how is the division to be decided? The incomes of individuals are determined by the quantities of resources (labour skills, capital in all its forms) they own and the prices they receive for the use of these resources. Workers are incited by the price system to acquire new skills and to exercise them diligently, and families are encouraged to savings (capital accumulation) by the payment of interest or dividends. The inheritance of both personal ability and wealth also enter into the distribution of income.

If the price system is working reasonably well (some of the common failures will be noted later), it performs all of these economic functions with remarkable subtlety and precision. Society desires not only the correct amount of wheat but also that it be consumed more or less evenly over the crop year, with a surplus to carry over in case of a partial failure of the next year's crop. The price system provides a seasonal price pattern that encourages the holding of inventories rather than early splurging and richly rewards speculators who correctly anticipate a crop failure and hold grain that will alleviate it. In the same way, the desires of every sizable group of consumers (or resource owners) are registered through the price system; entrepreneurs are incited by price offers to provide opera and musical comedy, kosher food, and Persian delicacies. One might almost say that the price system is devoted to minority rule, since the only pressure toward uniformity is in the possibility of lowering costs of production by standardizing goods.

High prices in a properly functioning price system thus serve as incentives to produce more and consume less, and lower prices serve as corresponding deterrents. In addition the price system is a method of communicating information. Herbert Spencer once stated, rather ponderously, that only by constant iteration can alien truths be impressed upon reluctant minds: the price system, with its capacity for infinite repetition, is well suited to this sometimes unpleasant task. A higher price of steel scrap, for example, tells thousands of owners and collectors of scrap that more scrap is wanted and that more exhaustive search for abandoned rails, boilers, radiators, and machines is worth undertaking. A higher price of gasoline tells thousands of automobile drivers that gasoline should be used more sparingly, and the message is repeated each time each driver purchases more gasoline.

THE WORKINGS OF THE PRICE SYSTEM

The complexity and variety of tasks performed by the price system will be illuminated by an examination of three specific economic problems.

The choice of occupation. Individuals must be distributed among occupations in such a way as to serve two basic purposes. First, the labourer must be placed where he is most productive—making certain that Enrico Fermi becomes a physicist rather than a chef and that there are not too many plumbers and too few electricians. Second, the individual worker should be given an occupation that is congenial to him: since he will spend a large part of his life at work, it will be a better life if he can choose the type he prefers.

The price of labour

The price of labour is the instrument by which workers are distributed among occupations: wages in rapidly growing occupations and rapidly growing parts of the nation are higher than in corresponding employment in declining occupations and areas. The choice of occupation involves, however, much more than simply a comparison of wage rates. The following are a few of the complications: (1) The wages of an occupation must as a rule be sufficient to compensate the costs of training. (2) The wages of an occupation must be sufficient to compensate special disadvantages (such as a large chance of unemployment). (3) Wages must be higher in large cities than in small because living costs are higher in large cities. (4) Wages must compensate workers for their additional skill as they acquire experience (they usually reach a peak of earnings between ages 40 and 55) and thereafter decline as the worker's efficiency declines. (5) Wages will reflect differences in taxation, fringe benefits (pensions, vacations), etc. Accordingly the wage structure even for a single occupation in a single city is elaborate. When a single wage (price) is imposed upon an occupation, labourers are no longer properly distributed by wages; for example, a city school system that pays all teachers of given experience the same wage finds it difficult to staff its less attractive schools.

The preferences of the individual worker cannot be given full play, or each person would become president of the corporation at a sumptuous salary. Yet the labourer may choose to live in California rather than Maine; then the price system will incite employers to move their operations to California, where they can hire this labourer more cheaply. The labourer may prefer to work long hours or short hours, and employers are induced by wage offers to cater to the labourer's diverse preferences. In fact it is equally appropriate to speak of the worker buying conditions of work and of the employer buying the services of the worker.

The conservation of resources. A society has some resources that can be replaced by investment: timber is now largely grown as a commercial crop. Farmland is a more ancient example: the fertility of soil can be increased by prudent cultivation. Other resources are not replaceable, such as coal and petroleum. How does the price system conserve these exhaustible resources?

Pricing and conservation

The method of using a resource is independent of the pattern over time of income and expenditures that the owner of the resource desires. Suppose that a farm will have a value of $100,000 if it is maintained at a constant level of fertility and yields a yearly income of $10,000 forever but that it can be cultivated ("mined") intensively to yield $12,000 a year for five years at the cost of a much reduced yield thereafter, with a value of $90,000. Even if the farmer is in urgent need of immediate funds

and does not expect to live more than five years, he will still cultivate the farm at the uniform rate. Only then is it worth its maximum value to him, and only then (by sale or mortgage) can he obtain the largest possible funds even in the near future. In short, one need not adapt his expenditure pattern to his income pattern so long as he can borrow or lend.

If the growth of consumption or the decline of reserves threaten the exhaustion of supplies of a resource, then the price of that resource will rise and promise to rise more in the future, and this rise will serve to reduce current consumption and to reward the owner of the resource for holding back much of the supply for the future. This rise in price will therefore also stimulate buyers to find more economical ways of using the commodity (for example, burning the fuel more efficiently) and stimulate producers to find new supplies or substitute products. The price system will, therefore, ensure that the supply of the resource will be stretched out so that the resource will be available in both the present and the future.

LIMITATIONS AND FAILURES OF THE PRICE SYSTEM

The price system is an extraordinarily powerful instrument in organizing an economic system, but it is subject to three broad classes of limitations.

Private and public price control. Sometimes prices are not permitted to do their work. Monopolies are able to exert control over prices; and they use it, sensibly enough, to raise their profits above the level allowed by competition. The monopolist (or group of colluding enterprises) sets prices at a level such that prices are above costs or, to use words of identical significance, such that resources earn more in the monopolized industry than they can earn elsewhere. The basis of the monopoly is its ability to prevent outsiders from entering the industry to share in the unusual profits and, by the act of producing, actually serve to eliminate them.

The cost of monopoly

The fixing of prices by monopolists reduces the income of society. This is, in fact, the only well-established criticism (on grounds of efficiency) to be levied against monopolies: there is no reason to assume that they will make products less suited to consumer tastes or innovate more slowly or pay lower wages or otherwise misallocate resources. But the basic inefficiency led, first in the United States in 1890 and then increasingly in European nations, to governmental policies to maintain or restore competition.

Public price control has two aspects. A large part of public regulation is intended to correct monopolistic pricing (or other failures of the price system); this includes most public-utility regulation in the United States (transportation, electricity, and gas, etc.). Whatever the success of these endeavours—and on the whole there has been a substantial decline in confidence in the regulatory bodies—they are usually instructed to achieve the goals of an efficient price system.

Other public price controls are designed to serve ends outside the reach of the price system. Prices of farm products are regulated (raised) in most nations with the intention of improving farmers' incomes, and the fixing of interest rates paid by banks is undertaken to improve bank earnings. Such policies are invariably defended on various economic and ethical grounds but reflect primarily the political strength of large and well organized producer groups.

Externalities and the price system. A second class of limitations consists of things that should be done but are not performable by a price system. Even when prices are freely established by competition, there is a class of economic relationships called "externalities" not efficiently controlled by prices. These may be illustrated by the air pollution caused by automobiles. Since no single automobile makes a significant contribution to air pollution, the owner has no incentive to bear the cost of installing antipollution devices even though all drivers would be better off if each did so. Yet if there are many automobiles in a region, it would be prohibitively expensive for drivers to contract with one another to have each install devices in his automobile to reduce pollution. The external effects of any one automobile's exhaust fumes are so diffuse and affect any one person so triflingly that they cannot be regulated by the price system.

The class of "externalities" is as broad as the class of actions that have effects upon people who are not parties to the contracts governing the actions. An attractive garden pleases passers-by, but they cannot be charged a portion of its cost. A new piece of scientific knowledge will prove useful to unknown persons. These two examples indicate that some externalities are economically trivial and some are highly important.

When the price system cannot deal with diffused effects, other social controls often take its place. The state invokes a whole arsenal of policies to deal with externalities, of which the following are only examples: (1) The state may subsidize activities that do not end in a product that can be sold. Thus basic scientific research that does not lead to patentable processes is subsidized. (2) Individuals may be compelled to act uniformly in areas where contracts would be too expensive; traffic laws, zoning laws, and compulsory vaccination are examples. (3) The state may itself undertake an activity that cannot be financed by sale of services, the most obvious example being national defense.

Traffic congestion and prices

An interesting type of externality is the problem of highway congestion. Any one person's presence on a highway at a time and place of peak density has only a negligible effect upon others, so that, except on toll roads, private contracts have not been feasible. The state itself has not been able to deal effectively with highway congestion. More highways can be built until no highway is ever crowded, but this would be intolerably expensive. The state has lacked a method of inducing drivers to shift to less crowded hours and routes by charging fees to those drivers who impose high congestion costs by driving at peak times. Recent developments in technology may make it feasible to use the price system to reduce congestion. For example, cameras at appropriate points could photograph automobile licenses and a computer could accumulate the charges based on route and time for each automobile. Then only a person for whom travel at peak times was worth, for example, 25 cents per mile would impose (and pay for) the congestion he created.

Imperfect knowledge and tastes. A third class of limitations to which the price system is subject has to do with the control of knowledge and tastes. To the extent that an economic actor, whether a consumer, a labourer, or an investor, is poorly informed, he is likely to make decisions whose consequences are much different from those he desired and expected. What follows relates only to consumer decisions, but parallel issues arise in labour markets, securities markets, etc.

A consumer can satisfy his desires only if he makes intelligent purchases—that is, only if the goods he buys are what he believes them to be. How can the consumer know whether the meat is free of disease or whether the washing machine will function well and long or whether the fabric of the garment is one synthetic fibre or another? To ascertain these facts personally, the consumer would have to be a versatile scientist equipped with a superb laboratory—and then he would need to spend so much time testing goods that he would have little time to enjoy them.

In some measure the consumer does experiment in his buying: whenever he buys a thing repeatedly, experience tells him much concerning its properties. Direct experience is a sufficient guide in buying celery or hiring domestic servants, but usually the purchase of information takes a less direct form. The city's premier department store can sell at prices somewhat higher than less well-known retailers; and the difference represents the payment of a price for reliability, responsibility, and the guarantee of quality. In parallel fashion the consumer buys the washing machine of a company that made his excellent refrigerator. Occasionally, information is bought directly: the advice of a lawyer, the knowledge of an appraiser, the taste of an interior decorator.

The need for information

The most important and controversial method of informing consumers is by advertising. Many critics are outraged by the self-serving statements of sellers, some of whom indubitably provide irrelevance and deception rather than information. Yet the informational content of advertising

may not be as deficient as its critics believe: advertising itself meets two market tests. In the first place, the direct sale of information by consumer advisory services has never become important, although there are no obstacles to entering this business. In the second place, there has been a general, sustained improvement in the quality of consumer goods over time: the automobile tire goes many more miles than formerly; the airplane flies more safely. Nevertheless, recent public policy has paid great attention to increasing the safety of products and to raising the accuracy of advertising claims.

Knowledge is sometimes difficult to distinguish from taste: does the consumer who persists in smoking cigarettes have inadequate knowledge or simply different comparative values for the pleasures and risks of smoking? Censorship, in any event, is fairly common in every economic system: no society allows young children or incompetents full freedom of action or allows the unlimited sale of narcotics. Since the price system never forbids an effective demand (a demand backed by a willingness to pay the supply price), some form of restriction of prices is, therefore, necessary if certain tastes are to be forbidden or restricted. Compulsory school attendance can be viewed as, in effect, a form of censorship; and so are the controls on sale of firearms and the taxes on tobacco and liquor.

NONCAPITALIST PRICE SYSTEMS

The foregoing discussion has been confined to the price system as it exists in capitalist economies. The Communist countries have prices, but not autonomous price systems; in those countries the direction of economic activity is largely in the hands of the central authorities, and prices are used mainly as a marketing device. None of the three allocative functions of an economy—determination of what will be produced, of how it will be produced, and of who will get the product—is performed by the price mechanism in the socialist economies.

"Shadow prices"

The relative scarcities that money prices measure exist, of course, in all countries and would exist in a world where no money or exchanges were allowed. Robinson Crusoe had a problem of allocating his time between sleep, garnering food, building shelter, etc.; and he confronted implicit costs of extending any one activity, for more food meant less of other things. The economist calls these implicit exchange ratios "shadow prices," and they appear in all areas of life in which deliberate choices are made.

Price systems are therefore the result of scarcity. The basic proposition of economics, that scarcities are essentially ubiquitous, is often phrased as "there is no such thing as a free lunch"; and it reminds one that the price of the lunch may be future patronage, a reciprocal lunch, or a boring monologue. The task of economic organization is the task of devising price systems that allow a society to achieve its basic goals. (G.J.S.)

Market structure: competition, oligopoly, monopoly

When economists use such words as "competition" and "monopoly" they have in mind certain complex relations among firms in an industry. An industry, as economists define it, is a group of sellers of close-substitute products who supply a common group of buyers. For the economy as a whole an industry would include all sellers having this relation. Thus one can recognize a cigarette or automobile or aluminum industry—in all, hundreds of industries.

TYPES OF MARKET STRUCTURES

Different industries have different market structures—that is, different market characteristics that determine the relations of sellers to one another, of sellers to buyers, and so forth. Probably the most important aspects of market structure are (1) the degree of concentration of sellers in an industry, (2) the degree of product differentiation, and (3) the ease or difficulty with which new sellers can enter the industry.

Seller concentration refers to the number of sellers in an industry together with their comparative shares of industry sales. When the number of sellers is quite large, and each seller's share of the market is so small that in practice he cannot, by changing his selling price or output, perceptibly influence the market share or income of any competing seller, economists speak of *atomistic competition.* A more common situation is that of *oligopoly,* in which the number of sellers is so few that the market share of each is large enough for even a modest change in price or output by one seller to have a perceptible effect on the market shares or incomes of rival sellers, and to cause them to react to the change. In a broader sense, oligopoly exists in any industry in which at least some sellers have large shares of the market, even though there may be an additional number of small sellers. When a single seller supplies the entire output of an industry, and thus can determine his selling price and output without concern for the reactions of rival sellers, a *single-firm monopoly* exists.

Product differentiation

The structure of a market is also affected by the extent to which those who buy from it prefer some products to others. In some industries the products are regarded as identical by their buyers—as, for example, basic farm crops. In others the products are differentiated in some way so that various buyers prefer various products. Notably, the criterion is a subjective one; the buyers' preferences may have little to do with tangible differences in the products but are related to advertising, brand names, and distinctive designs. The degree of product differentiation as registered in the strength of buyer preferences ranges from slight to fairly large, tending to be greatest among infrequently purchased consumer goods and "prestige goods," particularly those purchased as gifts.

Industries vary in the ease with which new sellers can enter them. The barriers to entry consist of the advantages that sellers already established in an industry have over the potential entrant. Such a barrier is generally measurable by the extent to which established sellers can persistently elevate their selling prices above minimal average costs without attracting new sellers. The barriers may exist because costs for established sellers are lower than they would be for new entrants, or because the established sellers can command higher prices from buyers who prefer their products to those of potential entrants. The economics of the industry also may be such that new entrants would have to be able to command a substantial share of the market before they could operate profitably.

The effective height of these barriers varies. One may distinguish three rough degrees of difficulty in entering an industry: *blockaded entry,* which allows established sellers to set monopolistic prices, if they wish, without attracting entry; *impeded entry,* which allows established sellers to raise their selling prices above minimal average costs without attracting new sellers, but not as high as a monopolist's price; and *easy entry,* which does not permit established sellers to raise their prices at all above minimal average costs without attracting new entrants.

This discussion of market characteristics suggests a general way of classifying industries according to their market structures:

I. Atomistic competition
  A. With homogeneous products—"pure competition"
  B. With differentiated products—"monopolistic competition"
II. Oligopoly
  A. With homogeneous products—"pure oligopoly"
    1. With blockaded entry
    2. With impeded entry
    3. With easy entry
  B. With differentiated products—"heterogeneous oligopoly"
    1. With blockaded entry
    2. With impeded entry
    3. With easy entry
III. Single-firm monopoly
  A. With blockaded entry
  B. With impeded entry

Under atomistic competition, in which entry is generally easy, there are no barriers to entry. By the same token, product differentiation among sellers is obviously inconsistent with single-firm monopoly.

The comparative importance of these types of market structure differs among various sectors of the economy.

In the manufacturing sector in the United States, which includes about 400 industries, single-firm monopolies are almost completely absent. But in more than half of the manufacturing industries there is enough seller concentration for them to qualify as oligopolies. The remaining industries are more or less atomistic in their market structure. An appreciable degree of product differentiation is found in about half of the oligopolistic industries and in about half of the atomistic industries. Very strong product differentiation is usually found among oligopolistic industries. Easy entry is typical of atomistic industries, impeded entry of oligopolies. Entry is probably blockaded in a minor fraction of the latter, generally those with very high seller concentration.

The proportions of oligopolistic and atomistic manufacturing industries are about the same in the United Kingdom as in the United States. The incidence of oligopolies is slightly higher in Japan and progressively higher in France, Italy, Canada, and Sweden. Single-firm monopolies in manufacturing are found in a few industries in some of these countries, but they are typically under government ownership.

In the public-utility sector in the United States, single-firm monopolies are typically found in industries supplying gas, electricity, and telephone and telegraph service. Oligopoly, frequently highly concentrated, is typical in the radio and television and transportation industries; entry into these industries is usually very difficult or blockaded. The significance of such structural conditions is lessened, however, by the fact that these industries are subject to various degrees of public regulation. The situation is much the same in other Western countries, except that public utilities are frequently under government ownership.

In the distributive trades (wholesaling and retailing), a number of United States industries are fairly atomistic, while a somewhat larger number are relatively unconcentrated oligopolies in which a few large sellers supply about half the industry's output and a very large number of small sellers supply the remainder. Product differentiation is important. Entry is relatively easy. The service-trade industries in the United States display a similar range of characteristics. In the distributive- and service-trade sectors in other Western countries, oligopoly is less frequent and atomistic industries are proportionally more important. The residential-construction industries in the U.S. and elsewhere are relatively atomistic in structure, have significant product differentiation, and are easy to enter. Industries in the agricultural sectors of Western countries generally are typically atomistic in structure, with easy entry. But the significance of these structural conditions is lessened by governmental interference designed to modify the working of market forces.

MARKET CONDUCT AND PERFORMANCE

Sellers' behaviour in different market structures

How do sellers behave in determining their selling prices, outputs, advertising costs, and so forth; and in what ways does this market behaviour differ among industries with different types of market structure? An educated layman might ask, for example, whether sellers cut their selling prices in order to take customers away from each other until some rock-bottom market price is reached just high enough to allow them minimal interest returns on their investments or whether, on the other hand, they agree with each other to set a uniform higher price well above their production costs, sharing the market and reaping excessive profits.

It is helpful to distinguish the related ideas of *market conduct* and *market performance*. Market conduct refers to the price and other market policies pursued by sellers, in terms both of their aims and of the way in which they coordinate their decisions and make them mutually compatible. Market performance refers to the end results of these policies—the relationship of selling price to costs, the size of output, the efficiency of production, progressiveness in techniques and products, and so forth.

Pure competition. Market conduct and performance in atomistic industries provide good standards against which to measure behaviour in other types of industry. The atomistic category includes both pure competition and monopolistic competition. In pure competition, a large number of small sellers supply a homogeneous product to a common buying market. In this situation no individual seller can perceptibly influence the market price at which he sells but must accept a market price that is impersonally determined by the total supply of the product offered by all sellers and the total demand for the product of all buyers. The large number of sellers precludes the possibility of a common agreement among them, and each must therefore act independently. At any going market price, each seller tends to adjust his output to that quantity that will yield him the largest aggregate profit, assuming that the market price will not change as a result. But the collective effect of such adjustments by all sellers will cause the total supply in the market to change significantly so that the market price falls or rises. Theoretically, the process will go on until a market price is reached at which the total output that sellers wish to produce is equal to the total output that all buyers wish to purchase. This way of reaching a provisional equilibrium price is what Adam Smith was referring to when he wrote of prices being determined by "the invisible hand" of the market.

The competitive ideal

If the provisional equilibrium price is high enough to allow the established sellers profits in excess of a normal interest return on investment, then added sellers will be drawn to enter the industry, and supply will increase until a final equilibrium price is reached that is equal to the minimal average cost of production (including an interest return) of all sellers. Conversely, if the provisional equilibrium price is so low that established sellers incur losses, some will tend to withdraw from the industry, and supply will decline until the same sort of long-run equilibrium price is reached.

The long-run performance of a purely competitive industry therefore embodies these features: (1) industry output is at a feasible maximum and industry selling price at a feasible minimum; (2) all production is undertaken at minimum attainable average costs, since competition forces them down; and (3) income distribution is not influenced by the receipt of any excess profits by sellers.

This performance has often been applauded as ideal from the standpoint of general economic welfare. But the applause, for several reasons, should not be unqualified. Pure competition is truly ideal only if all or most industries in the economy are purely competitive and if in addition there is free and easy mobility of productive factors among industries. Otherwise, the relative outputs of different industries will not be such as to maximize consumer satisfaction. There is also some question whether producers in purely competitive industries will generally earn enough to plow back some of their earnings into improved equipment and thus maintain a satisfactory rate of technological progress. Finally, some purely competitive industries have been afflicted with "destructive competition"—the coal industry and the basic agricultural industries, for example. For some historical reason such an industry accumulates excess capacity to the point where sellers suffer chronic losses, and the situation is not corrected by the exit of people and resources from the industry. The invisible hand of the market works too slowly for society to accept. In some cases, notably in agriculture, government has intervened to restrict supply or raise prices. Leaving these qualifications aside, however, the market performance of pure competition furnishes some sort of a standard to which the performance of industries of different structure may be compared.

Monopolistic competition. In the more complex situation of monopolistic competition (atomistic structure with product differentiation) market conduct and performance may be said to follow roughly the tendencies attributed to pure competition. The principal differences are the following. First, individual sellers, because of the differentiation of their products, are able to raise or lower their individual selling prices slightly; they cannot do so by very much, however, because they remain strongly subject to the impersonal forces of the market operating through the general level of prices. Second, rivalry among sellers is likely to involve sales promotion costs as well as the expense of altering products to appeal to buyers. This is

a competitive game that all will play but that nobody, on the average, will win, and the long-run equilibrium price will reflect the added costs involved. In return, however, buyers will get more variety. Third, since not every seller is likely to be equally successful in his sales-promotion and product policies, some will receive profits in excess of a basic interest return on their investment; such profits will come from their success in winning buyers. Monopolistic competition may, like pure competition, include industries that are afflicted with what has been called above destructive competition. This may result not only from a failure to get rid of excess capacity but also from the entry of too many new firms despite the danger of losses.

Monopoly. While single-firm monopolies are rare, except for those subject to public regulation, it is useful to examine the monopolist's market conduct and performance to establish a standard at the other pole from pure competition. As the sole supplier of a distinctive product, the monopolist can set any selling price provided he accepts the sales that correspond to that price. Since the market demand will generally be less the higher the price he sets, the monopolist presumably will set that price that produces the greatest profits, given the relationship of production costs to output. By restricting output he can raise his selling price significantly—an option not open to sellers in atomistic industries.

Monopolistic behaviour

The monopolist will generally charge prices well in excess of production costs and reap profits well above a normal interest return on investment. His output will be substantially smaller, and his price higher, than if he had to meet established market prices as in pure competition. The monopolist may or may not produce at minimal average cost, depending on his cost–output relationship; if he does not, there are no market pressures to force him to do so.

If the monopolist is subject to no threat of entry by a competitor, he will presumably set a selling price that maximizes profits for the industry he monopolizes. If he faces only impeded entry, he may elect to charge a price sufficiently low to discourage entry but above a competitive price—if this will maximize his long-run profits.

Oligopoly. Market conduct and performance in oligopolistic industries generally combine monopolistic and competitive tendencies, with the relative strength of the two tendencies depending roughly on the detailed market structure of the oligopoly.

Rivalry among sellers. In the simplest form of oligopolistic industry, sellers are few and every seller supplies a sufficiently large share of the market so that any feasible and modest change in his policies will appreciably affect the market shares of all his rival sellers and induce them to react or respond. For example, if seller A reduces his selling price below the general level of prices being charged by all sellers sufficiently to permit him to capture significant numbers of customers from his rivals if they hold their selling prices unchanged, they may react by reducing their prices by a similar amount, so that none gains at the expense of others and the group has probably reduced its combined profits. Or seller A's rivals may retaliate by reducing their selling prices more than he did, thus forcing a further reaction from him. Conversely, if seller A increases his selling price above the general level being charged by all sellers (thus tending to lose at least some of his customers to his rivals), they may react by holding their prices unchanged, in which event seller A will probably retract his increase and bring his price back to the previous level. But his rivals may also react by raising their prices as much as seller A raised his, in which case the general level of prices in the industry rises and the combined profits of all sellers are probably increased.

Any seller A in an oligopoly will therefore determine whether or not to alter his price or other market policy in the light of his conjectures about the reactions of his rivals. Correspondingly, his rivals will determine their reactions in the light of their conjectures about what seller A will do in response. The process is not likely to bring the industry price level down to minimal average cost (as in atomistic competition). Many different "equilibrium" levels between the competitive and monopolistic limits are possible, depending on further circumstances.

Thus in an oligopoly viable collusive agreements among rival sellers are quite possible. They may be express agreements established by contract or tacit understandings that develop as a pattern of reactions among sellers to changes in each others' prices or market policies becomes customary. In the United States, express collusive agreements are forbidden by law, but tacit agreements or "gentlemen's understandings" are common in oligopolies. In numerous other Western countries, formal collusive agreements (often called cartels if comprehensive in scope) are legal. Whether tacit or explicit, legal or illegal, one may say that oligopolistic prices tend to be "administered" by sellers, in the senses mentioned above, as distinct from being determined by impersonal market forces.

Sellers' dual aims. The varying market performance of oligopolies results from the fact that individual sellers intrinsically have two conflicting aims. One common desire is to establish among themselves a monopolistic level of price (and of selling costs, etc.), which will maximize their combined profits, giving them the largest "profit pie" to divide. But each seller also has a fundamental antagonism toward rival sellers and wants to maximize his own profits even at the expense of theirs. The relative strengths of these conflicting aims—the maximizing of combined profits and the maximizing of individual profits—will likely depend on how concentrated the oligopoly is, because when sellers are fewer and their individual market shares larger, their rivals' reactions are stronger deterrents to independent actions.

Price behaviour in oligopoly

This is why various sorts of market performance are to be expected in oligopolistic industries. When the entry of other sellers is blockaded, collusive or interdependent behaviour may lead to a full monopoly price. If entry is only impeded, the resulting price may be far enough below the full monopoly level to discourage further entry. But prices are not always what they seem. An announced price that is well above cost may be undercut by clandestine price reductions to individual buyers, bringing the average of actual selling prices down somewhat.

If an oligopolistic industry is made up of a "core" of a few large interdependent sellers plus a "competitive fringe" of several or numerous quite small sellers, the competition of the small sellers may induce the large ones to limit the extent to which they raise their prices.

Price behaviour approaching full monopoly pricing seems to be found mainly in oligopolies having very high seller concentration and blockaded entry. Where these characteristics are less pronounced, prices and profits tend to be lower, though they are likely to be somewhat above the competitive level. A few economists maintain that oligopolistic prices in general do not significantly differ from atomistically competitive prices, but the bulk of statistical evidence does not support them.

In oligopolies in which product differentiation is important, sales-promotion costs and the costs of product improvement or development will display roughly the same variety of tendencies found in pricing. Where there are a few large interdependent sellers, these costs may be restricted to about the same level as those of a single-firm monopolist; on the other hand, rivalry in sales promotion and product development may be sufficient to raise them higher. Oligopolists may also arrive collusively at relatively high uniform selling prices but simultaneously engage in independent nonprice competition (perhaps more so where seller concentration is lower).

WORKABLE COMPETITION

Since the character of market performance varies among industries along with their market characteristics, efforts have been made to devise some practical standard for identifying the sorts of market structure that engender socially satisfactory performance in a given industry. The term workable competition was coined to denote competition that may be considered as leading to a reasonable or socially acceptable approximation to ideal performance in the circumstances of a particular industry. The limits of such an approximation are of course debatable, and so the idea of workable competition must remain elusive because it is basically subjective.

Five attributes of workable competition

Without entering into a complex theoretical discussion of the relationship of individual-industry performance to overall welfare, it is plausible to suggest the following principal attributes of workable performance in an industry: (1) In the long term, selling price on the average should be equal to or not significantly above average costs of production, so that profits do not appreciably exceed a normal interest return on investment. Prices should be responsive to basic reductions in costs. (2) In so far as average costs of production are affected by the scales or capacities of plants and firms, the preponderance of industry output should be from plants and firms of the most efficient scale or with closely comparable technical efficiency. (3) The industry should not have chronic excess capacity—*i.e.*, significant plant capacity that is persistently unused even in periods of high general economic activity. (4) The industry's sales-promotion costs should not be substantially greater than needed to keep buyers informed of the availability, characteristics, and prices of products. (5) The industry should be adequately progressive in introducing more economical production techniques and improved products—balancing the costs of progress with the gains.

While the first three of these attributes are easier to appraise than the others, certain generalizations are possible concerning the workability of different market structures: (1) Unregulated single-firm monopolies tend to generate unworkable market performance, mainly in the form of output restriction, prices well above costs, and consequent excess profits. They have undesirable effects on the uses to which resources are put and on income distribution. (2) Oligopolies with high seller concentration and also very high barriers to entry tend toward unworkable performance, like that of single-firm monopoly. In general, however, they do not show significant degrees of technical inefficiency resulting from inefficient plant scales or excess capacity. (3) Oligopolies with fairly high seller concentration but only moderate barriers to entry are also prone to unworkable performance of the sort just mentioned, but not to as high a degree. (4) Oligopolies with only moderate seller concentration and moderate-to-low barriers to entry tend toward workable performance both in price–cost relations and in technical efficiency, except that some of them may have recurrent chronic excess capacity due to periodic overentry. (If cartels are legalized and their provisions are not rigorously controlled by government, the last two categories of oligopoly may have the same sort of unworkable performance as do very highly concentrated oligopolies.) (5) Industries of atomistic structure tend generally toward workable performance unless they suffer from destructive competition as described above.

Product differentiation and promotion

In industries with significant differentiation of products among sellers—and especially in oligopolies of this sort—there is a tendency for minor but significant fractions of income to be devoted to persuasive (as distinct from informational) advertising and other sales promotion and also to more or less idle variations of product design, with the result that resources are in a sense "wasted" and costs increased.

By the criteria of workable competition, a purely rational society would presumably favour industries with moderate to low seller concentration, moderate to low barriers to entry, and without extreme product differentiation—all this from the standpoint of enhancing overall material welfare. The argument that oligopolistic and atomistic industries generally need legal protection from destructive competition may be discarded on the basis of evidence. Price and other market warfare in such industries has been extremely rare in industrial countries in the last 50 years.

(J.S.B./Ed.)

Production: the output of the factors of production

In economics, the theory of production is an effort to explain the principles by which a business firm decides how much of each commodity that it sells (its "outputs" or "products") it will produce, and how much of each kind of labour, raw material, fixed capital good, etc., that it employs (its "inputs" or "factors of production") it will use. The theory involves some of the most fundamental principles of economics. These include the relationship between the prices of commodities and the prices (or wages or rents) of the productive factors used to produce them and also the relationships between the prices of commodities and productive factors, on the one hand, and the quantities of these commodities and productive factors that are produced or used, on the other.

The various decisions a business enterprise makes about its productive activities can be classified into three layers of increasing complexity. The first layer includes decisions about methods of producing a given quantity of the output in a plant of given size and equipment. It involves the problem of what is called short-run cost minimization. The second layer, including the determination of the most profitable quantities of products to produce in any given plant, deals with what is called short-run profit maximization. The third layer, concerning the determination of the most profitable size and equipment of plant, relates to what is called long-run profit maximization.

MINIMIZATION OF SHORT-RUN COSTS

The relationship between input and output

The production function. However much of a commodity a business firm produces, it endeavours to produce it as cheaply as possible. Taking the quality of the product and the prices of the productive factors as given, which is the usual situation, the firm's task is to determine the cheapest combination of factors of production that can produce the desired output. This task is best understood in terms of what is called the production function, *i.e.*, an equation that expresses the relationship between the quantities of factors employed and the amount of product obtained. It states the amount of product that can be obtained from each and every combination of factors. This relationship can be written mathematically as $y=f(x_1, x_2, \ldots, x_n; k_1, k_2, \ldots, k_m)$. Here, y denotes the quantity of output. The firm is presumed to use n variable factors of production; that is, factors like hourly paid production workers and raw materials, the quantities of which can be increased or decreased. In the formula the quantity of the first variable factor is denoted by x_1 and so on. The firm is also presumed to use m fixed factors, or factors like fixed machinery, salaried staff, etc., the quantities of which cannot be varied readily or habitually. The available quantity of the first fixed factor is indicated in the formal by k_1 and so on. The entire formula expresses the amount of output that results when specified quantities of factors are employed. It must be noted that though the quantities of the factors determine the quantity of output, the reverse is not true, and as a general rule there will be many combinations of productive factors that could be used to produce the same output. Finding the cheapest of these is the problem of cost minimization.

The cost of production is simply the sum of the costs of all of the various factors. It can be written:

$$C=p_1x_1+\cdots+p_nx_n+r_1k_1+\cdots+r_nk_n,$$

in which p_1 denotes the price of a unit of the first variable factor, r_1 denotes the annual cost of owning and maintaining the first fixed factor, and so on. Here again one group of terms, the first, covers variable cost (roughly "direct costs" in accounting terminology), which can be changed readily; another group, the second, covers fixed cost (accountants' "overhead costs"), which includes items not easily varied. The discussion will deal first with variable cost.

The principles involved in selecting the cheapest combination of variable factors can be seen in terms of a simple example. If a firm manufactures gold necklace chains in such a way that there are only two variable factors, labour (specifically, goldsmith-hours) and gold wire, the production function for such a firm will be $y=f(x_1, x_2; k)$, in which the symbol k is included simply as a reminder that the number of chains producible by x_1 feet of gold wire and x_2 goldsmith-hours depends on the amount of machinery and other fixed capital available. Since there are only two variable factors, this production function can be portrayed graphically in a figure known as an isoquant diagram (Figure 8). In the graph, goldsmith-hours per

month are plotted horizontally and the number of feet of gold wire used per month vertically. Each of the curved lines, called an isoquant, will then represent a certain number of necklace chains produced. The data displayed show that 100 goldsmith-hours plus 900 feet of gold wire can produce 200 necklace chains. But there are other combinations of variable inputs that could also produce 200 necklace chains per month. If the goldsmiths work more carefully and slowly, they can produce 200 chains from 850 feet of wire; but to produce so many chains more goldsmith-hours will be required, perhaps 130. The isoquant labelled "200" shows all the combinations of the variable inputs that will just suffice to produce 200 chains. The other two isoquants shown are interpreted similarly. It is obvious that many more isoquants, in principle an infinite number, could also be drawn. This diagram is a graphic display of the relationships expressed in the production function.

Substitution of factors. The isoquants also illustrate an important economic phenomenon: that of factor substitution. This means that one variable factor can be substituted for others; as a general rule a more lavish use of one variable factor will permit an unchanged amount of output to be produced with fewer units of some or all of the others. In the example above, labour was literally as good as gold and could be substituted for it. If it were not for factor substitution there would be no room for further decision after y, the number of chains to be produced, had been established.

The shape of the isoquants shown, for which there is a good deal of empirical support, is very important. In moving along any one isoquant, the more of one factor that is employed, the less of the other will be needed to maintain the stated output; this is the graphic representation of factor substitutability. But there is a corollary: the more of one factor that is employed, the less it will be possible to reduce the use of the other by using more of the first. This is the property known as "diminishing marginal rates of substitution." The marginal rate of substitution of factor 1 for factor 2 is the number of units by which x_1 can be reduced per unit increase in x_2 output remaining unchanged. In the diagram, if feet of gold wire

Diminishing marginal rate of substitution

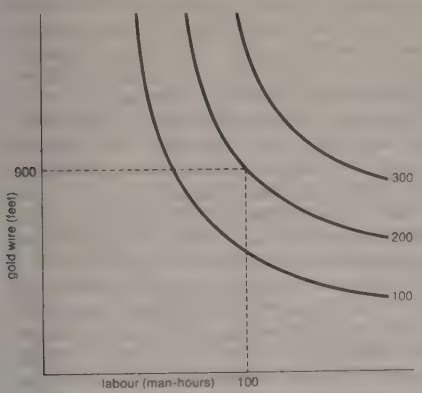

Figure 8: Isoquant diagram of hours of labour and feet of gold wire used per month.

are indicated by x_1 and goldsmith-hours by x_2, then the marginal rate of substitution is shown by the steepness (the negative of the slope) of the isoquant; and it will be seen that it diminishes steadily as x_2 increases because it becomes harder and harder to economize on the use of gold simply by taking more care. The remainder of the analysis rests heavily on the assumption that diminishing marginal rates of substitution are characteristic of the production process generally.

The cost data and the technological data can now be brought together. The variable cost of using x_1, x_2 units of the factors of production is written $p_1x_1 + p_2x_2$, and this information can be added to the isoquant diagram (Figure 9). The straight line labelled v_2, called the v_2-isocost line, shows all the combinations of input that can be purchased for a specified variable cost, v_2. The other two isocost lines shown are interpreted similarly. The general formula for an isocost line is $p_1x_1 + p_2x_2 = v$, in which v is some particular variable cost. The slope of an isocost line is found by dividing p_2 by p_1 and depends only on the ratio of the prices of the two factors.

The minimization of costs

Three isocost lines are shown, corresponding to variable costs amounting to v_1, v_2, and v_3. If 200 units are to be produced, expenditure of v_1 on variable factors will not suffice since the v_1-isocost line never reaches the isoquant for 200 units. An expenditure of v_3 is more than sufficient: and v_2 is the lowest variable cost for which 200 units can be produced. Thus v_2 is found to be the minimum variable cost of producing 200 units (as v_3 is of 300 units) and the coordinates of the point where the v_2 isocost line touches the 200-unit isoquant are the quantities of the two factors

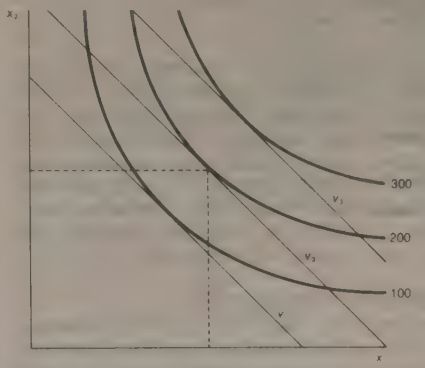

Figure 9: Isoquant diagram for two factors of production, x_1 and x_2 (see text).

that will be used when 200 units are to be produced and the prices of the two factors are in the ratio p_2/p_1. It may be noted that the cheapest combination for the production of any quantity will be found at the point at which the relevant isoquant is tangent to an isocost line. Thus, since the slope of an isoquant is given by the marginal rate of substitution, any firm trying to produce as cheaply as possible will always purchase or hire factors in quantities such that the marginal rate of substitution will equal the ratio of their prices.

The isoquant–isocost diagram (or the corresponding solution by the alternative means of the calculus) solves the short-run cost minimization problem by determining the least-cost combination of variable factors that can produce a given output in a given plant. The variable cost incurred when the least-cost combination of inputs is used in conjunction with a given outfit of fixed equipment is called the variable cost of that quantity of output and denoted $VC(y)$. The total cost incurred, variable plus fixed, is the short-run cost of that output, denoted $SRC(y)$. Clearly $SRC(y) = VC(y) + R(K)$, in which the second term symbolizes the sum of the annual costs of the fixed factors available.

Marginal cost. Two other concepts now become important. The average variable cost, written $AVC(y)$, is the variable cost per unit of output. Algebraically, $AVC(y) = VC(y)/y$. The marginal variable cost, or simply marginal cost $[MC(y)]$ is, roughly, the increase in variable cost incurred when output is increased by one unit; *i.e.*, $MC(y) = VC(y+1) - VC(y)$. Though for theoretical purposes a more precise definition can be obtained by regarding $VC(y)$ as a continuous function of output, this is not necessary in the present case.

The usual behaviour of average and marginal variable costs in response to changes in the level of output from a given fixed plant is shown in Figure 10. In this figure costs (in dollars per unit) are measured vertically and output (in units per year) is shown horizontally. The figure is drawn for some particular fixed plant, and it can be seen that average costs are fairly high for very low levels of output relative to the size of the plant, largely because there is not enough work to keep a well-balanced work force fully occupied. People are either idle much of the time or shifting, expensively, from job to job. As output increases from a low level, average costs decline to a low plateau. But as the capacity of the plant is approached, the inefficiencies

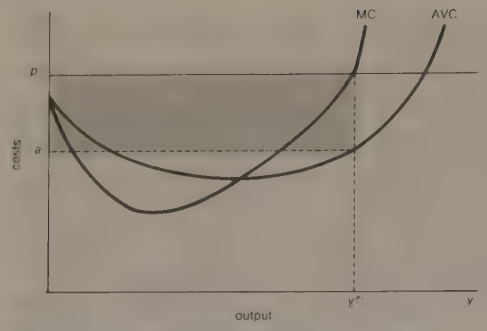

Figure 10: Average variable costs (AVC) and marginal variable costs (MC) in relation to output.

incident on plant congestion force average costs up quite rapidly. Overtime may be incurred, outmoded equipment and inexperienced hands may be called into use, there may not be time to take machinery off the line for routine maintenance; or minor breakdowns and delays may disrupt schedules seriously because of inadequate slack and reserves. Thus the AVC curve has the flat-bottomed U-shape shown. The MC curve, as might be expected, falls faster and rises more rapidly than the AVC curve.

MAXIMIZATION OF SHORT-RUN PROFITS

The average and marginal cost curves just deduced are the keys to the solution of the second-level problem, the determination of the most profitable level of output to produce in a given plant. The only additional datum needed is the price of the product, say p_0.

How the firm maximizes its profit

The most profitable amount of output may be found by using these data. If the marginal cost of any given output (y) is less than the price, sales revenues will increase more than costs if output is increased by one unit (or even a few more); and profits will rise. Contrariwise, if the marginal cost is greater than the price, profits will be increased by cutting back output by at least one unit. It then follows that the output that maximizes profits is the one for which $MC(y) = p_0$. This is the second basic finding: in response to any price the profit-maximizing firm will produce and offer the quantity for which the marginal cost equals that price.

Such a conclusion is shown in Figure 10. In response to the price, p_0, shown, the firm will offer the quantity y^* given by the value of y for which the ordinate of the MC curve equals the price. If a denotes the corresponding average variable cost, net revenue per unit will be equal to $p_0 - a$, and the total excess of revenues over variable costs will be $y^*(p_0 - a)$, which is represented graphically by the shaded rectangle in the figure.

Marginal cost and price. The conclusion that marginal cost tends to equal price is important in that it shows how the quantity of output produced by a firm is influenced by the market price. If the market price is lower than the lowest point on the average variable cost curve, the firm will "cut its losses" by not producing anything. At any higher market price, the firm will produce the quantity for which marginal cost equals that price. Thus the quantity that the firm will produce in response to any price can be found in Figure 10 by reading the marginal cost curve, and for this reason the marginal cost curve is said to be the short-run supply curve for the firm.

The short-run supply curve for a product—that is, the total amount that all the firms producing it will produce in response to any market price—follows immediately, and is seen to be the sum of the short-run supply curves (or marginal cost curves, except when the price is below the bottoms of the average variable cost curves for some firms) of all the firms in the industry. This curve is of fundamental importance for economic analysis, for together with the demand curve for the product it determines the market price of the commodity and the amount that will be produced and purchased.

One pitfall must, however, be noted. In the demonstration of the supply curves for the firms, and hence of the industry, it was assumed that factor prices were fixed. Though this is fair enough for a single firm, the fact is that if all firms together attempt to increase their outputs in response to an increase in the price of the product, they are likely to bid up the prices of some or all of the factors of production that they use. In that event the product supply curve as calculated will overstate the increase in output that will be elicited by an increase in price. A more sophisticated type of supply curve, incorporating induced changes in factor prices, is therefore necessary. Such curves are discussed in the standard literature of this subject.

Marginal product. It is now possible to derive the relationship between product prices and factor prices, which is the basis of the theory of income distribution. To this end, the marginal product of a factor is defined as the amount that output would be increased if one more unit of the factor were employed, all other circumstances remaining the same. Algebraically, it may be expressed as the difference between the product of a given amount of the factor and the product when that factor is increased by an additional unit. Thus if $MP_1(x_1)$ denotes the marginal product of factor 1 when x_1 units are employed, then $MP_1(x_1) = f(x_1 + 1, x_2, \ldots x_n; k) - f(x_1, x_2 \ldots x_n; k)$. The marginal products are closely related to the marginal rates of substitution previously defined. If an additional unit of factor 1 will increase output by f_1 units, for example, then one more unit of output can be obtained by employing $1/f_1$ more units of factor 1. Similarly, if the marginal product of factor 2 is f_2, then output will fall by one unit if the use of factor 2 is reduced by $1/f_2$ units. Thus output will remain unchanged, to a good approximation, if $1/f_1$ units of factor 1 are used to replace $1/f_2$ units of factor 2. The marginal rate of substitution is therefore f_2/f_1, or the ratio of the marginal products of the two factors. It has already been shown that the marginal rate of substitution also equals the ratio of the prices of the factors, and it therefore follows that the prices (or wages) of the factors are proportional to their marginal products.

The returns to the factors of production

This is one of the most significant theoretical findings in economics. To restate it briefly: factors of production are paid in proportion to their marginal products. This is not a question of social equity but merely a consequence of the efforts of businessmen to produce as cheaply as possible.

Further, the marginal products of the factors are closely related to marginal costs and, therefore, to product prices. For if one more unit of factor 1 is employed, output will be increased by $MP_1(x_1)$ units and variable cost by p_1; so the marginal cost of additional units produced will be $p_1/MP_1(x_1)$. Similarly, if additional output is obtained by employing an additional unit of factor 2, the marginal cost will be $p_2/MP_2(x_2)$. But, as shown above, these two numbers are the same; whichever factor i is used to increase output, the marginal cost will be $p_i/MP_i(x_i)$ and, furthermore, the firm will choose its output level so that the marginal cost will be equal to the price, p_0.

Therefore it has been established that $p_1 = p_0 MP_1(x_1)$, $p_2 = p_0 MP_2(x_2)$, . . . , or the price of each factor is the price of the product multiplied by its marginal product, which is the value of its marginal product. This, also, is a fundamental theorem of income distribution and one of the most significant theorems in economics. Its logic can be perceived directly. If the equality is violated for any factor, the businessman can increase his profits either by hiring units of the factor or by laying them off until the equality is satisfied, and presumably the businessman will do so.

The theory of production decisions in the short run, as just outlined, leads to two conclusions (of fundamental importance throughout the field of economics) about the responses of business firms to the market prices of the commodities they produce and the factors of production they buy or hire: (1) the firm will produce the quantity of its product for which the marginal cost is equal to the market price and (2) it will purchase or hire factors of production in such quantities that the price of the commodity produced multiplied by the marginal product of the factor will be equal to the cost of a unit of the factor. The first explains the supply curves of the commodities produced in an economy. Though the conclusions were deduced within the context of a firm that uses two factors of production, they are clearly applicable in general.

MAXIMIZATION OF LONG-RUN PROFITS

The relationship between the short run and the long run

The theory of long-run profit-maximizing behaviour rests on the short-run theory that has just been presented but is considerably more complex because of two features: (1) long-run cost curves, to be defined below, are more varied in shape than the corresponding short-run cost curves, and (2) the long-run behaviour of an industry cannot be deduced simply from the long-run behaviour of the firms in it because the roster of firms is subject to change. It is of the essence of long-run adjustments that they take place by the addition or dismantling of fixed productive capacity by both established firms and new or recently created firms.

At any one time an established firm with an existing plant will make its short-run decisions by comparing the ruling price of its commodity with cost curves corresponding to that plant. If the price is so high that the firm is operating on the rising leg of its short-run cost curve, its marginal costs will be high—higher than its average costs—and it will be enjoying operating profits, as shown in Figure 10. The firm will then consider whether it could increase its profits by enlarging its plant. The effect of plant enlargement is to reduce the variable cost of producing high levels of output by reducing the strain on limited production facilities, at the expense of increasing the level of fixed costs.

In response to any level of output that it expects to continue for some time, the firm will desire and eventually acquire the fixed plant for which the short-run costs of that level of output are as low as possible. This leads to the concept of the long-run cost curve: the long-run costs of any level of output are the short-run costs of producing that output in the plant that makes those short-run costs as low as possible. These result from balancing the fixed costs entailed by any plant against the short-run costs of producing in that plant. The long-run costs of producing y are denoted by $\mathrm{LRC}(y)$. The average long-run cost of y is the long-run cost per unit of y [algebraically $\mathrm{LAC}(y) = \mathrm{LRC}(y)/y$]. The marginal long-run cost is the increase in long-run cost resulting from an increase of one unit in the level of output. It represents a combination of short-run and long-run adjustments to a slight increase in the rate of output. It can be shown that the long-run marginal cost equals the marginal cost as previously defined when the cost-minimizing fixed plant is used.

Classes of long-run cost curves

Cost curves appropriate for long-run analysis are more varied in shape than short-run cost curves and fall into three broad classes. In constant-cost industries, average cost is about the same at all levels of output except the very lowest. Constant costs prevail in manufacturing industries in which capacity is expanded by replicating facilities without changing the technique of production, as a cotton mill expands by increasing the number of spindles. In decreasing-cost industries, average cost declines as the rate of output grows, at least until the plant is large enough to supply an appreciable fraction of its market. Decreasing costs are characteristic of manufacturing in which heavy, automated machinery is economical for large volumes of output. Automobile and steel manufacturing are leading examples. Decreasing costs are inconsistent with competitive conditions, since they permit a few large firms to drive all smaller competitors out of business. Finally, in increasing-cost industries average costs rise with the volume of output generally because the firm cannot obtain additional fixed capacity that is as efficient as the plant it already has. The most important examples are agriculture and extractive industries.

CRITICISMS OF THE THEORY

The theory of production has been subject to much criticism. One objection is that the concept of the production function is not derived from observation or practice. Even the most sophisticated firms do not know the direct functional relationship between their basic raw inputs and their ultimate outputs. This objection can be got around by applying the recently developed techniques of linear programming, which employ observable data without recourse to the production function and lead to practically the same conclusions.

On another level the theory has been charged with excessive simplification. It assumes that there are no changes in the rest of the economy while individual firms and industries are making the adjustments described in the theory; it neglects changes in the technique of production; and it pays no attention to the risks and uncertainties that becloud all business decisions. These criticisms are especially damaging to the theory of long-run profit maximization. On still another level, critics of the theory maintain that businessmen are not always concerned with maximizing profits or minimizing costs.

Though all of the criticisms have merit, the simplified theory of production does nevertheless indicate some basic forces and tendencies operating in the economy. The theorems should be understood as conditions that the economy tends toward, rather than conditions that are always and instantaneously achieved. It is rare for them to be attained exactly, but it is just as rare for substantial violations of the theorems to endure.

Only the simplest aspects of the theory were described above. Without much difficulty it could be extended to cover firms that produce more than one product, as almost all firms do. With more difficulty it could be applied to firms whose decisions affect the prices at which they sell and buy (monopoly, monopolistic competition, monopsony). The behaviour of other firms that recognize the possibility that their competitors may retaliate (oligopoly) is still a theory of production subject to controversy and research. (R.D.)

Distribution: the shares of the factors of production

The factors of production, as suggested earlier, are the economic resources, both human and other, which, if properly utilized, will bring about a flow or output of goods and services. The factors are commonly classified into three groups: capital, labour, and land. The first, in the simplest sense, refers to all the "produced" instruments of production—the factories, their equipment, their stocks of raw materials and finished goods, houses, trade facilities, and so on; the owners of capital receive their income in various possible forms, profits and interest being the usual ones. The factor of labour represents all those productive resources that can be applied only at the cost of human effort; the wage (or salary) is the form of payment for use of this factor. The factor of land represents resources whose supply is low in relation to demand and cannot be increased as the result of production; the income derived from the ownership of this factor is known as economic rent.

Capital, labour, and land

Distribution, in economics, generally refers to (1) explanations of how prices for the services of the different factors of production are determined; (2) explanations of how the total product of the economy is divided among the various factors, and (3) descriptions of the ways in which the income is divided among various income classes or groups of persons.

CAPITAL AND INTEREST

Capital in economics is a word of many meanings. They all imply that capital is a "stock" by contrast with income, which is a "flow." In its broadest possible sense, capital includes the human population; nonmaterial elements such as skills, abilities, and education; land, buildings, machines, equipment of all kinds; and all stocks of goods—finished or unfinished—in the hands of both firms and households.

In the business world the word capital usually refers to an item in the balance sheet representing that part of the net worth of an enterprise that has not been produced through the operations of the enterprise. In economics the word capital is generally confined to "real" as opposed to merely "financial" assets. Different as the two concepts may seem, they are not unrelated. If all balance sheets were consolidated in a closed economic system, all debts would be cancelled out because every debt is an asset in one balance sheet and a liability in another. What is left in the consolidated balance sheet, therefore, is a value of all the

real assets of a society on one side and its total net worth on the other. This is the economist's concept of capital.

Kinds of capital

A distinction may be made between goods in the hands of firms and goods in the hands of households, and attempts have been made to confine the term capital structure to the former. There is also a distinction between goods that have been produced and goods that are gifts of nature; attempts have been made to confine the term capital to the former, though the distinction is hard to maintain in practice. Another important distinction is between the stock of human beings (and their abilities) and the stock of nonhuman elements. In a slave society human beings are counted as capital in the same way as livestock or machines. In a free society each man is his own slave—the value of his body and mind is not, therefore, an article of commerce and does not get into the accounting system. In strict logic persons should continue to be regarded as part of the capital of a society; but in practice the distinction between the part of the total stock that enters into the accounting system, and the part that does not, is so important that it is not surprising that many writers have excluded persons from the capital stock.

Another distinction that has some historical importance is that between circulating and fixed capital. Fixed capital is usually defined as that which does not change its form in the course of the process of production, such as land, buildings, and machines. Circulating capital consists of goods in process, raw materials, and stocks of finished goods waiting to be sold; these goods must either be transformed, as when wheat is ground into flour, or they must change ownership, as when a stock of goods is sold. This distinction, like many others, is not always easy to maintain. Nevertheless, it represents a rough approach to an important problem of the relative structure of capital; that is, of the proportions in which goods of various kinds are found. The stock of real capital exhibits strong complementarities. A machine is of no use without a skilled operator and without raw materials for it to work on.

The classical theory of capital. Although ancient and medieval writers were interested in the ethics of interest and usury, the concept of capital as such did not rise to prominence in economic thought before the classical economists (Adam Smith, David Ricardo, Nassau Senior, and John Stuart Mill).

The ideas of economists about capital

Adam Smith laid great stress on the role played by the accumulation of a stock of capital in facilitating the division of labour economics and in increasing the productivity of labour in general. He recognized clearly that accumulation proceeds from an excess of production over consumption. He distinguished between productive labour, which creates objects of capital, and unproductive labour (services), the fruits of which are enjoyed immediately. His thought was strongly coloured by observation of the annual agricultural cycle. The end of the harvest saw society with a given stock of grain. This stock was in the possession of the capitalists. A certain portion of it they reserved for their own consumption and for the consumption of their menial servants, the rest was used to feed "productive labourers" during the ensuing year. As a result, by the end of the next harvest the barns were full again and the stock had replaced itself, perhaps with something left over. The stock that the capitalists did not reserve for their own use was the "wages fund"—the more grain there was in the barn in October the sharper the competition of capitalists for workers, and the higher real wages would be in the year to come. The picture is a crude one, of course, and does not indicate the complexity of the relationship between stocks and flows in an industrial society. The last of the classical economists, John Stuart Mill, was forced to abandon the wages-fund theory. Nevertheless, the wages fund is a crude representation of some real but complex relationships, and the theory reappears in a more sophisticated form in later writers.

The classical economists distinguished three categories of income—wages, profit, and rent—and identified these with three factors of production—labour, capital, and land. David Ricardo especially made a sharp distinction between capital as "produced means of production," and land as the "original and indestructible powers of the soil." In modern economics this distinction has become blurred.

The Austrian school. About 1870 a new school developed, sometimes called the Austrian school from the fact that many of its principal members taught in Vienna, but perhaps better called the Marginalist school. The movement itself was thoroughly international, and included such figures as William Stanley Jevons in England and Léon Walras in France. The so-called Austrian theory of capital is mainly based on the work of Eugen Böhm-Bawerk. His *Positive Theory of Capital* (1889) set off a controversy that has not yet subsided. In the Austrian view the economic process consisted of the embodiment of "original factors of production" in capital goods of greater or lesser length of life that then yielded value or utility as they were consumed. Between the original embodiment of the factor and the final fruition in consumption lay an interval of time known as the period of production. In an equilibrium population it can easily be shown that the total population (capital stock) equals the annual number of births or deaths (income) multiplied by the average length of life (period of production). The longer the period of production, therefore, the more capital goods there will be per unit of income. If the period of production is constant, income depends directly on the amount of capital previously accumulated. Here is the wages fund in a new form. Unfortunately, the usefulness of Böhm-Bawerk's theory is much impaired by the fact that it is confined to equilibrium states. The great problems of capital theory are dynamic in character, and comparative statics throws only a dim light on them.

Marginalist and Keynesian theories. The Marginalist school culminated in the work of three men—P.H. Wickstead in England, Knut Wicksell in Sweden, and Irving Fisher in the United States. The last two especially gave the Austrian theory clear mathematical expression. Perhaps the greatest contribution of the Austrian theory was its recognition of the importance of the valuation problem in the relation of capital to interest. From the mere fact that physical capital produces an income stream, there is no explanation of the phenomenon of interest, for the question is why the value of a piece of physical capital should be less than the total of future values that are expected to accrue from it. The theory also makes a contribution to the problem of rational choice in situations involving waiting or maturing. The best example is that of slowly maturing goods such as wines or timber. There is a problem here of the best time to draw wine or to cut down a tree. According to the marginal theory this is at the time when the rate of net value growth of the item is just equal to the rate of interest, or the rate of return in alternative investments. Thus, if a tree or a wine is increasing in value at the rate of 7 percent per annum when the rate of interest is 6 percent it still pays to be patient and let it grow or mature. The longer it grows, however, the less the rate of value growth, and when the rate of value growth has fallen to the rate of interest, then is the time to reap the fruits of patience.

Growth and marginal value

The contributions of John Maynard (Lord) Keynes to capital theory are incidental rather than fundamental. Nevertheless, the "Keynesian revolution" had an impact on this area of economic thought as on most others. It overthrew the traditional assumption of most economists that savings were automatically invested. The great contribution of Keynes, then, is the recognition that the attempt to save does not automatically result in the accumulation of capital. A decision to restrict consumption is only a decision to accumulate capital if the volume of production is constant. If abstention from consumption itself results in a diminution of production, then accumulation (production minus consumption) is correspondingly reduced.

Important theoretical questions

Later thinking. The theory of capital was not a matter of primary concern to economists in the late 20th century, though some revival of interest occurred in the late 1950s. Nevertheless, certain problems remain of perennial interest. They may be grouped as follows.

Heterogeneous goods. First are the problems involved in measuring aggregates of goods. Real capital includes everything from screwdrivers to continuous strip-rolling mills. A single measure of total real capital can be achieved only

if each item can be expressed in a common denominator such as a given monetary unit (*e.g.*, dollars, sterling, francs, pesos, etc.). The problem becomes particularly complicated in periods of rapid technical change when there is change not only in the relative values of products but in the nature of the list itself. Only approximate solutions can be found to this problem, and no completely satisfactory measure is ever possible.

A related problem that has aroused considerable interest among accountants is how to value capital assets that have no fixed price. In the conventional balance sheet the value of some items is based on their cost at an earlier period than that of others. When the general level of prices is changing this means that different items are valued in monetary units of different purchasing power. The problem is particularly acute in the valuation of inventory. Under the more conventional "FIFO" (First In, First Out) system, inventory is valued at the cost (purchase price) of the latest purchases. This leads to an inflation of inventory values, and therefore of accounting profits, in time of rising prices (and a corresponding deflation under falling prices), which may be an exaggeration of the long-run position of the firm. This may be partially avoided by a competing system of valuation known as LIFO (Last In, First Out), in which inventory is valued at the purchase price of the earliest purchases. This avoids the fluctuations caused by short-run price-level changes, but it fails to record changes in real long-run values. There seems to be no completely satisfactory solution to this problem, and it is wise to recognize the fact that any single figure of capital value that purports to represent a complex, many-dimensional reality will need careful interpretation.

The accumulation process. A second problem concerns the factors that determine the rate of accumulation of capital; that is, the rate of investment. It has been seen that investment in real terms is the difference between production and consumption. The classical economist laid great stress on frugality as the principal source of capital accumulation. If production is constant it is true that the only way to increase accumulation is by the reduction of consumption. Keynes shifted the emphasis from the reduction of consumption to the increase of production, and regarded the decision to produce investment goods as the principal factor in determining the rate of growth of capital. In modern theories of economic development great stress is laid on the problem of the structure of production—the relative proportions of different kinds of activity. The advocates of "balanced growth" emphasize the need for a developing country to invest in a wide range of related and cooperative enterprises, public as well as private. There is no point in building factories and machines, they say, if the educational system does not provide a labour force capable of using them. There is also, however, a case to be made for "unbalanced growth," in the sense that growth in one part of the economy frequently stimulates growth in other parts. A big investment in mining or in hydroelectric power, for example, creates strains on the whole society, which result in growth responses in the complementary sectors. The relation of inflation to economic growth and investment is an important though difficult problem. There seems to be little doubt that deflation, mainly because it shifts the distribution of income away from the profit maker toward the *rentier* and bondholder, has a deleterious effect on investment and the growth of capital. In 1932, for instance, real investment had practically ceased in the United States. It is less clear at what point inflation becomes harmful to investment. In countries where there has been long continuing inflation there seems to be some evidence that the structure of investment is distorted. Too much goes into apartment houses and factories and not enough into schools and communications.

Effects of deflation and inflation

Capital and time. A third problem that exists in capital theory is that of the period of production and the time structure of the economic process. This cannot be solved by the simple formulas of the Austrian school. Nevertheless, the problem is a real one and there is still a need for more useful theoretical formulations of it. Decisions taken today have results extending far into the future. Similarly, the data of today's decisions are the result of decisions that were taken long in the past. The existing capital structure is the embodiment of past decisions and the raw material of present decisions. The incompatibility of decisions is frequently not discovered at the time they are made because of the lapse of time between the decision and its consequences. It is tempting to regard the cyclical structure of human history, whether the business cycle or the war cycle, as a process by which the consequences of bad decisions accumulate until some kind of crisis point is reached. The crisis (a war or a depression) redistributes power in the society and so leads to a new period of accumulating, but hidden, stress. In this process, distortion in the capital structure is of great importance.

Capital and income. A fourth problem to be considered is the relationship that exists between the stocks and the flows of a society, or in a narrower sense the relation between capital and income. Income, like capital, is a concept that is capable of many definitions; a useful approach to the concept of income is to regard it as the gross addition to capital in a given period. For any economic unit, whether a firm or an individual, income may be measured by that hypothetical amount of consumption that would leave capital intact. In real terms this is practically identical with the concept of production. The total flow of income is closely related to both the quantity and the structure of capital; the total real income of a society depends on the size and the skills of its population, and on the nature and the extent of the equipment with which they have to work. The most important single measure of economic well-being is real income per person; this is closely related to the productivity of labour, and this in turn is closely related to capital per person, especially if the results of investment in human resources, skills, and education are included in the capital stock.

Interest. Historically, the concept of capital has been so closely bound to the concept of interest that it seems wise to take these two topics together, even though in the modern view it is capital and income rather than capital and interest that are the related concepts. The nature of interest

Interest as a form of income may be defined as income that is received as a result of the possession of contractual obligations for payment on the part of another. Interest, in other words, is income that is received as a result of the ownership of a bond, a promissory note, or some other instrument that represents a promise on the part of some other party to pay sums in the future. The obligations may take many forms. In the case of the perpetuity, the undertaking is to pay a certain sum each year or other interval of time for the indefinite future. A bond with a date of maturity usually involves a promise to pay a certain sum each year for a given number of years, and then a larger sum on the terminal date. A promissory note frequently consists of a promise to pay a single sum at a date that is some time in the future.

If $a_1, a_2, \ldots a_n$ are the sums received by the bondholder in years $1, 2 \ldots n$, and if P_0 is the present value in year 0, or the sum for which the bond is purchased, the rate of interest r in the whole transaction is given by the equation

$$P_o = a_1(1+r)^{-1} + a_2(1+r)^{-2} + \cdots + a_n(1+r)^{-n}.$$

There is no general solution for this equation, though in practice it can be solved easily by successive approximation, and in special cases the equation reduces to much simpler forms. In the case of a promissory note, for instance, the equation reduces to the form

$$P_o = a_n(1+r)^{-n}, \text{ or } \log(1+r) = \frac{\log a_n - \log P_o}{n}$$

where a_n is the single promised payment. In the case of a perpetuity with an annual payment of a, the formula reduces to

$$P_o = a[(1+r)^{-1} + (1+r)^{-2} + \cdots \text{ to inf.}] = \frac{a}{r}$$

whence $r = \dfrac{a}{P}$.

Thus if one had to pay $200 to purchase a perpetual annuity of $5 per annum, the rate of interest would be 2½ percent.

It should be observed that the dimensions of the rate of

interest are those of a rate of growth. The rate of interest is not a price or ratio of exchange; it is not itself determined in the market. What is determined in the market is the price of contractual obligations or "bonds." The higher the price of a given contractual obligation, the lower the rate of interest on it. Suppose, for instance, that one has a promissory note that is a promise to pay one $100 in one year's time. If I buy this for $100 now, the rate of interest is zero; if I buy it for $95 now the rate of interest is a little over 5 percent; if I buy it for $90 now, the rate of interest is about 11 percent. The rate of interest may be defined as the gross rate of growth of capital in a contractual obligation.

A distinction is usually made between interest and profit as forms of income. In ordinary speech, profit usually refers to income derived from the ownership of aggregates or assets of all kinds organized in an enterprise. This aggregate is described by a balance sheet. In the course of the operations of the enterprise, the net worth grows, and profit is the gross growth of net worth. Stocks, as opposed to bonds, usually imply a claim on the profits of some enterprise.

Interest theory since Aristotle

The development of interest theory. In ancient and medieval times the main focus of inquiry into the theory of interest was ethical, and the principal question was the moral justification of interest. On the whole, the taking of interest was regarded unfavourably by both classical and medieval writers. Aristotle regarded money as "barren" and the medieval schoolmen were hostile to usury. Nevertheless, where interest fulfilled a useful social function elaborate rationalizations were developed for it. Among the classical economists, the focus of attention shifted away from ethical justification toward the problem of mechanical equilibrium. The question then became this: Is there any equilibrium rate of interest or rate of profit in the sense that where actual rates are above or below this, forces are brought into play, tending to change them toward the equilibrium? The classical economists did not provide any clear solution for this problem. They believed that the rate of interest simply followed the rate of profit, for people would not borrow or incur contractual obligations unless they could earn something more than the cost of the borrowing by investing the proceeds in enterprises or aggregates of real capital. They believed that the growth of capital itself would tend to reduce the rate of profit because of the competition of the capitalists. This doctrine is important in the Marxian dynamics in which the struggle of capital to avoid a falling rate of profit is seen as a critical factor leading, for instance, to unemployment, foreign investment, and imperialism.

In the framework of classical economics, the work of Nassau Senior deserves mention. He raised the question whether profit or interest were "paid for" anything; that is, whether there was any identifiable contribution to the general product of society that would not be forthcoming if this form of income were not paid. He identified such a function and called it abstinence. Karl Marx denied the existence of any such function and argued that the social product must be attributed entirely to acts of labour, capital being merely the embodied labour of the past. On this view, profit and interest are the result of pure exploitation in the sense that they consist of an income derived from the power position of the capitalist and not from the performance of any service. Non-Marxist economists have generally followed Senior in finding some function in society that corresponds to these forms of income.

The Marginalists generally held that profit and interest were related to the marginal productivity of the extension of the period of production. Böhm-Bawerk assumed that "roundabout" processes of production would generally be more productive than processes with shorter periods of production; he thought there was a productivity of "waiting" (to use the term of Alfred Marshall) and saw the rate of interest as an inducement to the capitalist to extend the period of production.

A low rate of interest leads to concentration on longer, more roundabout processes, and a high rate of interest on shorter, less roundabout processes. There is a limit, however, on the period of production imposed by the existing stock of accumulated capital. If one embarks on a long process with insufficient capital, he will find that he has exhausted his resources before the end of the process and before the fruits can be gathered. It is the business of the rate of interest to prevent this, and to adjust the roundaboutness of the processes used to the capital resources available. The Marginalists' theory of interest reached its clearest expression in the work of Irving Fisher. He saw an equilibrium rate of interest as determined by the interaction of two sets of forces: the impatience of consumers on the one hand, and the returns from extending the period of production on the other.

John Maynard Keynes brought a new approach. His liquidity preference theory of interest is a short-run theory of the price of contractual obligations ("bonds"), and it is essentially an application of the general theory of market price. If people as a whole decide that they want to hold a larger proportion of their assets in the form of money, and if new money is not created to satisfy this desire, there will be a net desire to sell securities and the price of securities will fall. This is the same thing as a rise in the rate of interest. Conversely, if people want to get rid of money the price of securities will rise and the rate of interest will fall. This, then, is the theory of the "market" rate of interest, by contrast with the Marginalists' theory, which concerns itself with whether or not there is a long-run equilibrium rate of interest. The controversy, therefore, between the liquidity preference theory—which regards interest as a "bribe" to prevent people holding money rather than bonds—and the time preference theory—which regards interest as a bribe to persuade people to postpone enjoyments to the future—can be resolved by placing the former in the short run and the latter in the long run.

Contemporary questions. The middle of the 20th century saw a considerable shift in the focus of concern relating to the theory of interest. Economists seemed to lose interest in the equilibrium theory, and their main concern was with the effect of rates of interest as a part of monetary policy in the control of inflation. It was recognized that the monetary authority could control the rate of interest in the short run. The controversy lay mainly between the advocates of "monetary policy" and the advocates of "fiscal policy." If inflation is regarded as a symptom of a desire on the part of a society to consume and invest more in total than its resources permit, it is clear that the problem can be attacked either by diminishing investment or by diminishing consumption. On the whole, the attack of the advocates of monetary policy is on the side of diminishing investment, through raising rates of interest and making it harder to obtain loans, though the possibility that high rates of interest may restrict consumption is not overlooked. The alternative would seem to restrict consumption by raising taxes. This has the disadvantage of being politically unpopular. The mounting concern with economic growth, however, has raised considerable doubts about the use of high rates of interest as an instrument to control inflation. There is some doubt whether high interest rates in fact restrict investment; if they do not, they are ineffective, and if they do, they may be harmful to economic growth. This is a serious dilemma for the advocates of monetary policy. On the other hand, it must be admitted that the type of fiscal policy that might be most desirable theoretically has achieved very limited public support.

Interest rates and inflation

The problem of the ethics of interest is still unresolved after many centuries of discussion; as long as the institution of private property is accepted, the usefulness of borrowing and lending can hardly be denied. In the long historic process of inheritance, widowhood, gain and loss, by which the distribution of the ownership of capital is determined, there is no reason to suppose that the actual ownership of capital falls into the hands of those best able to administer it. Much of the capital of an advanced society, in fact, tends to be owned by elderly widows, simply because of the greater longevity of the female. Society, therefore, needs some machinery for separating the control of capital from its ownership. Financial instruments and financial markets are the principal agency for

The ethics of interest

performing this function. If all securities took the form of stocks or equities, it might be argued that contractual obligations (bonds), and therefore interest as a form of income, would not be necessary. The case for bonds and interest, however, is the case for specialization. There is a demand for many different degrees of ownership and responsibility, and interest-bearing obligations tap a market that would be hard to reach with equity securities; they are also peculiarly well adapted to the obligations of governments. The principal justification for interest and interest-bearing securities is that they provide an easy and convenient way for skilled administrators to control capital that they do not own and for the owners of capital to relinquish its control. The price society pays for this arrangement is interest.

There remains the problem of the socially optimum rate of interest. It could be argued that there is no point in paying any higher price than one needs to and that the rate of interest should be as low as is consistent with the performance of the function of the financial markets. This position, of course, would place all the burden of control of economic fluctuations on the fiscal system, and it is questionable whether this would be acceptable politically.

The ancient problem of "usury," in the form of the exploitation of the ignorant poor by moneylenders, is still important in many parts of the world. The remedy is the development of adequate financial institutions for the needs of all classes of people rather than the attempt to prohibit or even to limit the taking of interest. The complex structure of lending institutions in a developed society—banks, building societies, land banks, cooperative banks, credit unions, and so on—testifies to the reality of the service that the lender provides and that interest pays for. The democratization of credit—that is, the extension of the power of borrowing to all classes in society—is one of the important social movements of the 20th century.

(K.E.Bo.)

LABOUR AND WAGES

Wages and labour costs

Wages are income derived from human labour. Technically they cover all payments for the use of labour, mental or physical, but in ordinary usage the term excludes income of the self-employed and is restricted to compensation of employees. Occasionally fringe benefits are included, but generally they are not. The term is not fully synonymous with labour costs, which may include such items as cafeterias or meeting rooms maintained for the convenience of employees (such items are part of capital). Wages, in economic terms, however, do include remuneration in the form of extra benefits, such as paid vacations, holidays, and sick leave, as well as wage supplements in the form of pensions and health insurance paid for by the employer. A worker in covered industries also receives the protection of governmentally provided unemployment compensation, old-age pensions, and industrial accident compensation. Government services provided for workers are of even greater significance in European countries than in the United States and must be taken into account when comparisons of earnings are made.

Classical theories. Theories of wage determination and the share of labour in the gross national product have varied from time to time and have changed as the economic environment has changed. The body of thought referred to today as wage theories could not have emerged until the old feudal system had disappeared and the modern economy with its modern institutions had come into existence. Adam Smith, in *The Wealth of Nations* (1776), failed to propose a definitive theory of wages, but he anticipated several theories that were developed by others later. Smith thought that wages were determined in the marketplace through the law of supply and demand. Workers and employers would naturally follow their own self-interest; labour would be attracted to the jobs where labour was needed most, and the result would be the greatest overall benefit to the workers and to society. But Smith gave no precise analysis of the supply of and demand for labour; he discussed many elements that were involved but did not weave them into a consistent theoretical pattern.

Subsistence theory. Subsistence theories emphasize the supply aspects and neglect the demand aspects of the labour market. They hold that change in the supply of workers is the basic force that drives real wages to the minimum required for subsistence. Elements of a subsistence theory appear in *The Wealth of Nations*, where Smith wrote that the wages paid to workers had to be enough to allow them to live and to reproduce themselves. Smith was more optimistic, however, than the British classical economists, such as David Ricardo and Thomas Malthus, who followed him, for he implied that—at least in an advancing nation—the wage level would have to be above subsistence to permit the population to grow enough to supply the additional workers needed. Ricardo maintained a more rigid view. He wrote that the "natural price" of labour was the price necessary to enable the labourers to subsist and to perpetuate the race without increase or diminution. Ricardo's statement was consistent with the Malthusian theory of population, which held that population adjusts to the means of supporting it. The market price of labour could not vary from the natural price for long: if wages rose above subsistence, the number of workers would increase and bring the wage rates down; if wages fell below subsistence, the number of workers would decrease and bring the wage rates up. At the time that these economists wrote, most workers were actually living near the subsistence level, and population appeared to be trying to outrun the means of subsistence. The subsistence theory seemed to fit the facts; and, although Ricardo said that the natural price of labour was not fixed and might be changed if custom and habit moderated population increases in relation to food supply and other items necessary to maintain labour, later writers tended to subscribe to the basic idea and not to admit exceptions. Their inflexible and inevitable conclusion earned the theory the name "iron law of wages."

The "natural price" of labour

Wages-fund theory. Smith said that the demand for labour could not increase except in proportion to the increase of the funds destined for the payment of wages. Ricardo maintained that an increase in capital would result in an increase in demand for labour. Statements such as these foreshadowed the wages-fund theory, which held that a predetermined fund of wealth existed for the payment of wages. The size of the fund could be changed over periods of time, but at any given moment the amount was fixed, and the average wage could be determined simply by dividing the fund by the number of workers. Smith thought of the fund as surplus income of wealthy men—beyond the needs of their families and trade—which they would use to employ others. Ricardo thought of it in terms of capital—food, clothing, tools, raw materials, machinery, etc., necessary to give effect to labour. Regardless of the makeup of the fund, the obvious conclusion was that when the fund was large in relation to the number of workers, wages would be high. When it was relatively small, wages would be low. If population increased too rapidly in relation to food and other necessities (as outlined by Malthus), wages would be driven to the subsistence level. Therefore, it would be to the advantage of labour to help promote the accumulation of capital to enlarge the fund rather than to discourage it by forming labour organizations and making exorbitant demands. Also, it followed that legislation designed to raise wages would not be successful, for, with only a fixed fund to draw upon, increases gained by some workers could be maintained only at the expense of others.

This theory was generally accepted for 50 years by economists, including such well-known figures as Nassau William Senior and John Stuart Mill. W.T. Thornton, F.D. Longe, and Francis A. Walker were largely responsible for discrediting the theory during the decade following 1865. They pointed out that the demand for labour was not determined by a fund but was derived from the consumer demand for products. The proponents of the wages-fund doctrine had been unable to prove that there was a determinate wage fund, or any fund maintaining a predetermined relationship with capital or with the portion of the proceeds of labour's product paid out in wages. Actually the amount paid out depended upon a number of factors, including the bargaining power of labour. Yet,

in spite of these telling criticisms, the wages-fund theory continued to exercise an important influence until the end of the 19th century.

Marxian surplus-value theory. Karl Marx accepted Ricardo's labour theory of value, but he subscribed to a subsistence theory of wages for a different reason than that given by the classical economists. In Marx's mind, it was not the pressure of population that drove wages to the subsistence level but rather the existence of a large army of unemployed, which he blamed on the capitalists. He stated that the exchange value of any product was determined by the amount of labour time socially necessary to create it. He held that under the capitalistic system, labour was merely a commodity and could get only its subsistence. The capitalist, however, could force the worker to spend more time on his job than was necessary to earn his subsistence, and the excess product, or surplus value, thus created, was taken by the capitalist.

Product in excess of subsistence

From the point of view of classical theory, Marx's argument appeared persuasive, although the term "labour time socially necessary" hid some serious objections. The fatal blow came when the labour theory of value and Marx's subsistence theory of wages were found to be invalid. Without them, the surplus-value theory collapsed.

Residual-claimant theory. The residual-claimant theory holds that, after all other factors of production have received their share of the product, the amount left goes to the remaining factor. Adam Smith implied such a theory for wages, since he said that rent would be deducted first and profits next. Francis A. Walker in 1875 worked out a residual theory of wages in which the shares of the landlord, capitalist, and entrepreneur were determined independently and subtracted, thus leaving the remainder for labour in the form of wages. It should be noted, however, that any of the factors of production may be selected as the residual claimant, assuming that independent determinations may be made for the shares of the other factors. It is doubtful, therefore, that such a theory has much value as an explanation of wage phenomena.

Bargaining theory. The bargaining theory of wages holds that wages, hours, and working conditions are determined by the relative bargaining strength of the parties to the agreement. Smith hinted at such a theory when he noted that employers had greater bargaining strength than employees, because it was easier for employers to combine in opposition to employees' demands and also because employers were financially able to withstand the loss of income for a longer period than the employees. This idea was developed to a considerable extent by John Davidson, who argued, in 1898, that the determination of wages is an extremely complicated process involving numerous influences that interact to establish the relative bargaining strength of the parties. There is no one factor or single combination of factors that determines wages, and there is no one rate that necessarily prevails. Because there are many possibilities, there is a range of rates within which any number of rates may exist simultaneously. The upper limit of the range is set by the rate beyond which the employer refuses to hire certain workers. This rate is influenced by such considerations as the productivity of the workers, the competitive situation, the size of the investment, and the employer's estimate of future business conditions. The lower limit of the range is set by the rate below which the workers will not offer their services to the employer. This rate is influenced by such considerations as minimum wage legislation, the workers' standard of living, their appraisal of the employment situation, and their knowledge of rates paid to others. Neither the upper nor the lower limit is fixed, and either may move upward or downward. The rate or rates within the range are determined by relative bargaining power.

The bargaining theory is very attractive to labour organizations, for, contrary to the subsistence and wages-fund theories, it provides a very cogent reason for the existence of unions. The bargaining strength of a union is much greater than that of the members acting as individuals. Also there are situations (bilateral monopoly, for instance) under which theoretical analysis arrives at a range of wage rates rather than a determinate rate. The actual rate must depend upon relative bargaining power. It should be observed, however, that historically labour was able to improve its situation before its bargaining power became more effective through organization. Factors other than the relative bargaining strength of the parties must have been at work. The bargaining theory often gives an excellent explanation of a short-run situation, such as the existence of certain wage differentials, but over the long run it fails to provide an adequate understanding of the changes that have taken place in the average level of wages.

Short-run and long-run applications

Marginal-productivity theory and its critics. Toward the end of the 19th century, marginal-productivity analysis was applied not only to labour but to other factors of production as well. It was not a new idea as an explanation of wage phenomena, for Smith had observed that a relationship existed between wage rates and the productivity of labour, and Johann Heinrich von Thünen, a German economist, had worked out a marginal-productivity type of analysis for wages in 1826. The Austrian economists made important contributions to the marginal idea after 1870; and, building on these grounds, a number of economists in the 1890s, including Philip Henry Wicksteed in England and John Bates Clark in the United States, elaborated the idea into the marginal-productivity theory of distribution. It is likely that the disturbing conclusions drawn by Marx from classical economic theory inspired this development. In the early 1930s refinements to the marginal-productivity analysis, particularly in the area of monopolistic competition, were made by Joan Robinson in England and Edward H. Chamberlin in the United States.

As applied to wages, the marginal-productivity theory holds that employers will tend to hire workers of a particular type until the addition made by the last (marginal) worker to the total value of the product is equal to the addition to total cost caused by the hiring of one more worker. The wage rate is established in the market through the demand for, and supply of, the type of labour, and the operation of competition assures the workers that they will receive a wage equal to the marginal product. Under the law of diminishing marginal productivity, the contribution of each additional worker is less than that of his predecessor, but workers of a particular type are assumed to be alike, making them interchangeable, and any one could be considered the marginal worker. All receive the same wage, and, therefore, by hiring to the margin, the employer maximizes his profits. As long as each additional worker contributes more to total value than he costs in wages, it pays the employer to continue hiring. Beyond the margin, additional workers would cost more than their contribution and would subtract from attainable profits.

The theory also provides an explanation of wage differentials. Wage differentials are caused by differences in marginal product. The wages of skilled workers are higher than those of unskilled workers because there are fewer skilled workers, and their marginal product, therefore, is higher.

The marginal-productivity theory of wages became the prevailing wage theory, and, although it has been attacked by many and discarded by some, no acceptable alternative has been devised. The chief basis for criticism of the theory is that it rests on unrealistic assumptions, such as the existence of homogenous groups of workers whose knowledge of the labour market is so complete that they will always move to the best job opportunities. Workers are, in fact, not homogenous; usually they have little knowledge of the labour market; and because of home ties, seniority, and other considerations, they do not often move quickly from one job to another. The assumption that employers are able to measure productivity accurately and compete freely in the labour market also is farfetched. Even the assumption that all employers attempt to maximize profits may be doubted. The profit motive does not affect charitable institutions or government agencies. For the theory to operate properly, labour and capital must be fully employed so that increased production can be secured only at increased cost; capital and labour must be easily substitutable for each other; and the situation must be completely competitive.

Theoretical weaknesses

Obviously these assumptions do not fit the real world, and some critics feel that the results of the theory are so misleading that the theory should be abandoned. The proponents argue, however, that productivity gives a rough approximation of wages, and that although productivity may not provide the immediate explanation in a particular case, it certainly indicates long-run trends. The theory, therefore, has important uses, and if the difficulties are kept in mind, it can be a valuable tool.

In a modern economy, monopolistic or near monopolistic conditions exist in some important areas, particularly where there are only a few large producers (such as in the automobile industry) on one side of the bargaining table and powerful labour organizations on the other. Under such circumstances, the marginal productivity analysis cannot determine wages precisely; it can show only the positions that the union (as a monopolist of labour supply) and the employer (as a monopsonist, or single purchaser of labour services) will strive to reach, depending upon their current policies.

Wages, consumption and employment

Purchasing-power theory. The purchasing-power theory of wages involves the relation between wages and employment and the business cycle and is not, therefore, a theory of wage determination. It stresses the importance of spending through consumption and investment as an influence upon the activity of the economy. The theory gained prominence during the Great Depression of the 1930s, when it became apparent that lowering wages might not increase employment as previously had been assumed. John Maynard Keynes, the British economist, maintained in his *General Theory of Employment, Interest and Money* (1936), that (1) depressional unemployment could not be explained merely by frictions in the labour market that interrupted the smooth movement of the economy toward full employment equilibrium and (2) the assumption that "all other things remained equal" presented a special case that had no real applicability to the existing situation. Keynes related changes in employment to changes in consumption and investment, and he pointed out that stable equilibrium could exist with less than full employment.

Because wages make up such a large percentage of the national income, changes in wages usually have an important effect upon consumption. It is possible that lowering wages will reduce consumption and that, with the decline in demand for goods and services, the demand for labour may also fall, thus decreasing employment rather than improving it. Whether this will be the result, however, depends upon several considerations, particularly the reaction upon prices. If wages fall more rapidly than prices, labour's real wages will be drastically reduced, and consumption will fall, accompanied by increased unemployment, unless total spending is maintained by increased investment. Entrepreneurs may look upon the lower wage costs in relation to prices as an encouraging sign toward greater profits, in which case they may increase their investments and employ more people at the lower rates, thus maintaining or even increasing total spending and employment. If employers look upon the falling wages and prices as an indication of further declines, however, they may contract their investments or do no more than maintain them. In this case, total spending and employment will decline.

If wages fall less rapidly than prices, labour's real wages will increase, and consumption may rise. If investment is at least maintained, total spending in terms of constant dollars will increase, thus improving employment. If entrepreneurs look upon the shrinking profit margin as a danger signal, however, they may reduce their investments; and, if the result is a reduction in total spending, employment will fall. If wages and prices fall the same amount, there should be no change in consumption and investment; and, in that case, employment will remain unchanged.

The purchasing-power theory involves psychological considerations as well as those that may be measured more objectively. Whether it can be used effectively to control the business cycle depends upon political as well as economic factors, because government expenditures are a part of total spending, taxes may affect private spending, etc. The applicability of the theory is to the whole economy rather than to the individual firm. (P.L.Kl.)

LAND AND RENT

Rent in economics is specially defined. According to the neoclassical economist Alfred Marshall, rent is the income derived from the ownership of land and other free gifts of nature. He, and others after him, chose this definition for technical reasons, even though it is somewhat more restrictive than the meaning given the term in popular usage. Apart from renting land, it is of course possible to rent (in other words, to pay money for the temporary use of any property) houses, automobiles, television sets, and lawn mowers on the understanding that the rented item is to be returned to its owner in essentially the same physical condition.

The more restrictive use of the term became popular rather early among writers on economic matters. For the classical economists of the 18th and 19th centuries, society was divided into three groups: landlords, labourers, and businessmen (or the "moneyed classes"). This division reflected more or less the sociopolitical structure of Great Britain at the time. The concern of economic theorists was to explain what determined the share of each class in the national product. The income received by landlords as owners of land was called rent.

It was observed that the demand for the product of land would make it profitable to extend cultivation to soils of lesser and lesser fertility, as long as the addition to the value of output would cover the costs of cultivation on the least fertile acreage cultivated. On land of greater fertility—intramarginal land—the costs of cultivation per unit of output would be below that price. This difference between cost and price could be appropriated by the owners of land, who benefitted in this way from the fertility of the soil—a "free gift of nature."

Marginal land (the least fertile cultivated) earned no rent. Since, therefore, it was differences in fertility that brought about the surplus for landowners, the return to them was called differential rent. It was also observed, however, that rent emerged not only as cultivation was pushed to the "extensi ve margin" (to less fertile acreage) but also as it was pushed to the "intensive margin" through more intensive use of the more fertile land. As long as the additional cost of cultivation was less than the addition to the value of the product, it paid to apply more labour and capital to any given piece of land until the net value of the output of the last unit of labour and capital hired had fallen to the level of its incremental cost. The intensive margin would exist even if all land were of equal fertility, as long as land was in scarce supply. It can be called scarcity rent, therefore, to contrast it with differential rent.

Extensive and intensive margins of production

However, because the return to any factor of production, not only to land, can be determined in the same way as scarcity rent, it was often asked why the return to land should be given a special name and special treatment. A justification was found in the fact that land, unlike other factors of production, cannot be reproduced. Its supply is fixed no matter what its price. Its supply price is effectively zero. By contrast, the supply of labour or capital is responsive to the price that is offered for it. With this in mind, rent was redefined as the return to any factor of production over and above its supply price.

With the supply price of land zero, the whole of its return is rent, so defined. The return to any other factor may also contain elements of rent, as long as the return stands above the next-most-lucrative employment open to the factor. For example, a singer's employment outside the opera may bring a great deal less than the opera actually pays. A large part of what the opera pays must therefore be called rent.

The opera singer's specific talent may be nonreproducible; like land, it is a "free gift of nature." A particularly effective machine also, though its supply can be increased in time by productive effort, may for a period also earn a quasi-rent, until supply has caught up with demand. Where its supply is artificially restricted by a monopoly, the quasi-rent may in fact continue indefinitely. All monopoly profits, it has been argued, should therefore be classified as

quasi-rent. Once this point has been reached in the argument, there is perhaps no logical barrier to extending the meaning of rent to cover all property returns. After all, profits and interest can persist only as long as there is no glut of capital. The possibility of producing capital would presage such a glut, one that has been staved off only by new scarcities created by technical progress.

(H.O.Sc.)

GENERAL THEORIES OF DISTRIBUTION

The division of the social product

The theory of distribution deals with the way in which a society's product is distributed among the members of that society. It involves three distinguishable sets of questions. First, how is the national income distributed among persons? How many persons earn less than $10,000, how many between $10,000 and $20,000, how many between $20,000 and $30,000, and so on? Are there regularities in these statistics? Is it possible to generalize about them? This is the problem of personal distribution. Second, what determines the prices of the factors of production? What are the influences governing the wage rate for a specific kind of labour? Why is the general wage level of a country not lower or higher than it is? What determines the rate of interest? What determines profits and rents? These questions have to do with functional distribution. Third, how is the national income distributed proportionally among the factors of production? What determines the share of labour in the national income, the share of capital, the share of land? This is the problem of distributive shares. Although the three sets of problems are obviously interrelated, they should not be confused with one another. The theoretical approaches to each of them involve quite different considerations.

Aspects of distribution. *Personal distribution.* Personal distribution is primarily a matter of statistics and the conclusions that can be drawn from them. When incomes are charted according to the number of people in each size category, the resulting frequency distribution is rather startling. Generally the top 10 percent of income receivers get between 25 and 35 percent of the national income, while the lowest 20 percent of the income receivers get about 5 percent of the national income. The inequality seems to be greatest in poor countries and diminishes somewhat in the course of economic development.

There are various explanations of the inequality. Some authorities point to the natural inequality of human beings (differences in intelligence and ability), others to the effects of social institutions (including education); some emphasize economic factors such as scarcity; others invoke political concepts such as power, exploitation, or the structure of society.

Distributive shares

For a long time economists were pessimistic as to the possibilities of any substantial improvement in the lot of those at the bottom of the income distribution. They generally held that the scarcity of productive land and the tendency of population to increase faster than the means of subsistence imposed limits on distributive justice. David Ricardo, in *On the Principles of Political Economy and Taxation* (1817), held that the landlords would receive an increasing part of the national income while capitalists would get less and less and that this shift in distribution would lead to economic stagnation. Karl Marx prophesied that the workers would be increasingly exploited and made miserable and that these conditions would lead to the downfall of capitalism. Neither prediction materialized. Thus in the Western world the share of rents has dwindled to a few percent of the national income, while the share of labour has gradually increased. For some time, economists believed that the share of labour was more or less constant, but investigations show that economic development is accompanied by an increasing share of labour. Though the statistics are complicated by technical problems, it is safe to say that in the United States, the share of wages rose from more than half the national income at the beginning of the century to more than 70 percent in the 1980s.

Contemporary approaches to this aspect of income distribution vary. Some are highly abstract and are closely related to the study of the whole, the modern macroeconomics of saving and investment. These will not be dealt with here. A simple common-sense approach employs an equation that starts by writing labour's share as the quotient of the total wage bill and the national income, $\text{labour's share} = \frac{\text{total wage bill}}{\text{national income}}$, and then writes the wage bill as the product of the wage level and the amount of labour (wage bill = wage level × amount of labour); next the national income is written as the product of the national output and the price level (national income = national output × price level); the result is that the share of labour equals the quotient of the average real wage rate and labour productivity, $\text{share of labour} = \frac{\text{average real wage rate}}{\text{labour productivity}}$, the latter being the quotient of the national output and the amount of labour: $\text{labour productivity} = \frac{\text{national output}}{\text{amount of labour}}$. If these two variables move in a parallel fashion, the share of labour is constant. If the real wage rate increases faster than the amount of labour productivity, the share of labour goes up. Similar reasoning applies to the shares of capital and land. This simple arithmetic is useful for an understanding of what happens in the real world, but for a profounder analysis one must turn to the theory of functional distribution.

Functional distribution. The theory of functional distribution, which attempts to explain the prices of land, labour, and capital, is a standard subject in economics. It sees the demand for land, labour, and capital as derived demand, stemming from the demand for final goods. Behind this lies the idea that a businessman demands inputs of land, labour, and capital because he needs them in the production of goods that he sells. The theory of distribution is thus related to the theory of production, one of the well-developed subjects of economics. The reasoning that synthesizes production and distribution theory is called neoclassical theory.

Components of the neoclassical, or marginalist, theory. The theory of marginal productivity

The basic idea in neoclassical distribution theory is that incomes are earned in the production of goods and services and that the value of the productive factor reflects its contribution to the total product. Though this fundamental truth was already recognized at the beginning of the 19th century (by the French economist J.B. Say, for instance), its development was impeded by the difficulty of separating the contributions of the various inputs. To a degree they are all necessary for the final result: without labour there will be no product at all, and without capital total output will be minimal. This difficulty was solved by J.B. Clark (*c.* 1900) with his theory of marginal products. The marginal product of an input, say labour, is defined as the extra output that results from adding one unit of the input to the existing combination of productive factors. Clark pointed out that in an optimum situation the wage rate would equal the marginal product of labour, while the rate of interest would equal the marginal product of capital. The mechanism tending to produce this optimum begins with the profit-maximizing businessman, who will hire more labour when the wage rate is less than the marginal product of additional workers and who will employ more capital when the rate of interest is lower than the marginal product of capital. In this view, the value of the final output is separated (imputed) by the marginal products, which can also be interpreted as the productive contributions of the various inputs. The prices of the factors of production are determined by supply and demand, while the demand for a factor is derived from the demand of the final good it helps to produce. The word derived has a special significance since in mathematics the term refers to the curvature of a function, and indeed the marginal product is the (partial) derivative of the production function.

One of the great advantages of the neoclassical, or marginalist, theory of distribution is that it treats wages, interest, and land rents in the same way, unlike the older theories that gave diverging explanations. (Profits, however, do not fit so smoothly into the neoclassical system.) A second advantage of the neoclassical theory

is its integration with the theory of production. A third advantage lies in its elegance: the neoclassical theory of distributive shares lends itself to a relatively simple mathematical statement.

An illustration of the mathematics is as follows. Suppose that the production function (the relation between all hypothetical combinations of land, labour, and capital on the one hand and total output on the other) is given as $Q = f(L,K)$ in which Q stands for total output, L for the amount of labour employed, and K for the stock of capital goods. Land is subsumed under capital, to keep things as simple as possible. According to the marginal productivity theory, the wage rate is equal to the partial derivative of the production function, or $\partial Q/\partial L$. The total wage bill is $(\partial Q/\partial L) \cdot L$. The distributive share of wages equals $(L/Q) \cdot (\partial Q/\partial L)$. In the same way the share of capital equals $(K/Q) \cdot (\partial Q/\partial K)$. Thus the distribution of the national income among labour and capital is fully determined by three sets of data: the amount of capital, the amount of labour, and the production function. On closer inspection the magnitude $(L/Q) \cdot (\partial Q/\partial L)$, which can also be written $(\partial Q/Q)/(\partial L/L)$, reflects the percentage increase in production resulting from the addition of 1 percent to the amount of labour employed. This magnitude is called the elasticity of production with respect to labour. In the same way the share of capital equals the elasticity of production with respect to capital. Distributive shares are, in this view, uniquely determined by technical data. If an additional 1 percent of labour adds 0.75 percent to total output, labour's share will be 75 percent of the national income. This proposition is very challenging, if only because it looks upon income distribution as independent of trade union action, labour legislation, collective bargaining, and the social system in general. Obviously such a theory cannot explain all of the real economic world. Yet its logical structure is admirable. What remains to be seen is the degree to which it can be used as an instrument for understanding the real economic world.

Application of the theory to reality

Criticisms of the neoclassical theory. *Returns to scale.* Neoclassical theory assumes that the total product Q is exactly exhausted when the factors of production have received their marginal products; this is written symbolically as $Q = (\partial Q/\partial L) \cdot L + (\partial Q/\partial K) \cdot K$. This relationship is only true if the production function satisfies the condition that when L and K are multiplied by a given constant then Q will increase correspondingly. In economics this is known as constant returns to scale. If an increase in the scale of production were to increase overall productivity, there would be too little product to remunerate all factors according to their marginal productivities; likewise, under diminishing returns to scale, the product would be more than enough to remunerate all factors according to their marginal productivities.

Research has indicated that for countries as a whole the assumption of constant returns to scale is not unrealistic. For particular industries, however, it does not hold; in some cases increasing returns can be expected, and in others decreasing returns. This situation means that the neoclassical theory furnishes at best only a rough explanation of reality.

One difficulty in assessing the realism of the neoclassical theory lies in the definition and measurement of labour, capital, and land, more specifically in the problem of assessing differences in quality. In macroeconomic reasoning one usually deals with the labour force as a whole, irrespective of the skills of the workers, and to do so leaves enormous statistical discrepancies. The ideal solution is to take every kind and quality of labour as a separate productive factor, and likewise with capital. When the historical development of production is analyzed it must be concluded that by far the greater part of the growth in output is attributable not to the growth of labour and capital as such but to improvements in their quality. The stock of capital goods is now often seen as consisting, like wine, of vintages, each with its own productivity. The fact that a good deal of production growth stems from improvements in the quality of the productive inputs leads to considerable flexibility in the distribution of the national income. It also helps to explain the existence of profits.

Substitution problems. Another difficulty arises from the fact that marginal productivity assumes that the factors of production can be added to each other in small quantities. If one must choose between adding one big machine or none at all to production, the concept of the marginal product becomes unworkable. This "lumpiness" creates an indeterminacy in the distribution of income. From the viewpoint of the individual firm, this objection to neoclassical theory is more serious than from the macroeconomic viewpoint since in terms of the national economy almost all additions to labour and capital are very small. A related problem is that of substitution among factors. The production function implies that land, labour, and capital can be combined in varying proportions, that every conceivable input mix is possible. But in some cases the input mix is fixed (*e.g.*, one operator at one machine), and in that situation the neoclassical theory breaks down completely because the marginal product for every factor is zero. These cases of fixed proportions are scarce, however, and from a macroeconomic viewpoint it is safe to say that a flexible input mix is the rule.

This is not to say that substitution between labour and capital is so flexible in the national economy that it can be assumed that a 1 percent increase in the wage rate will reduce employment by a corresponding 1 percent. That would follow from the neoclassical theory described above. It is not impossible, but it requires a very special form of the production function known as the Cobb–Douglas function. The pioneering research of Paul H. Douglas and Charles W. Cobb in the 1930s seemed to confirm the rough equality between production elasticities and distributive shares, but that conclusion was later questioned; in particular the assumption of easy substitution of labour and capital seems unrealistic in the light of research by Robert M. Solow and others. These investigators employ a production function in which labour and capital can replace each other but not as readily as in the Cobb–Douglas function, a change that has two very important consequences. First, the effect of a wage increase on the share of labour is not completely offset by changes in the input mix, so that an increase in wage rates does not lead to a proportionate reduction in total employment; and second, the factor of production that grows fastest will see its share in the national income diminished. The latter discovery, made by J.R. Hicks (1932), is extremely significant. It explains why the remuneration of capital (interest, not profits) has shrunk from 20 percent or more a century ago to less than 10 percent of the national income in modern times. In a society where more and more capital is employed in production, a continually smaller proportion of the income goes to the owners of capital. The share of labour has gone up; the share of land has gone down dramatically; the share of capital has gradually declined; and the share of profits has remained about the same. This picture of the historical development of income distribution fits roughly into the frame of neoclassical theory, although one must also make allowance for the short-run effects of inflation and the long-run effects of technological progress.

The analysis of earnings

Returns to the factors of production. The demand side of the markets for productive factors is explained in large degree by the theory of marginal productivity, but the supply side requires a separate explanation, which differs for land, labour, and capital.

Rent. The supply of land is unique in being rather inelastic; that is, an increase in rent does not necessarily increase the amount of available land. Landowners as a group receive what is left over after the other factors of production are paid. In this sense, rent is a residual, and a good deal of the history of the theory of distribution is concerned with the issue whether rent should be regarded as part of the cost of production or not (as in Ricardo's famous dictum that the price of corn is not high because of the rent of land but that land has a rent because the price of corn is high). But inelasticity of supply is not characteristic only of land; special kinds of labour and the size of the total labour force also tend to be unresponsive to variations in wages. The Ricardian issue, moreover, was important in the context of an agrarian society; it lacks

significance now, when land has so many different uses.

Wages. In analyzing the earnings of labour, it is necessary to take account of the imperfections of the labour market and the actions of trade unions. Imperfections in the market make for a certain amount of indeterminacy in which considerations of fairness, equity, and tradition play a part. These affect the structure of wages—*i.e.*, the relationships between wages for various kinds of labour and various skills. Therefore one cannot say that the income difference between a carpenter and a physician, or between a bank clerk and a truck driver, is completely determined by marginal productivity, although it is true that in the long run the wage structure is influenced by supply and demand.

Effects of labour unions

The role of the trade unions has been a subject of much debate. The naive view that unions can raise wages by their efforts irrespective of market forces is, of course, incorrect. In any particular industry, exaggerated wage claims may lead to a loss of employment; this is generally recognized by union leaders. The opposite view, that trade unions cannot influence wages at all (unless they alter the basic relationship between supply and demand for labour), is held by a number of economists with respect to the real wage level of the economy as a whole. They agree that unions may push up the money wage level, especially in a tight labour market, but argue that this will lead to higher prices and so the real wage rate for the economy as a whole will not be increased accordingly. These economists also point out that high wages tend to encourage substitution of capital for labour (the cornerstone of neoclassical theory). These factors do indeed operate to check the power of trade unions, although the extreme position that the unions have no power at all against the iron laws of the market system is untenable. It is safe to say that basic economic forces do far more to determine labour's share than do the policies of the unions. The main function of the unions lies rather in modifying the wage structure; they are able to raise the bargaining power of weak groups of workers and prevent them from lagging behind the others.

Interest and profit. The earnings of capital are determined by various factors. Capital stems from two sources: from saving (by households, financial institutions, and businesses) and from the creation of money by the banks. The creation of money depresses the rate of interest below what may be called its natural rate. At this lower rate, businessmen will invest more, the capital stock will increase, and the marginal productivity of capital will decline. Although this chain of reactions has drawn the attention of monetary theorists, its impact on income distribution is probably not very important, at least not in the long run. There are also other factors, such as government borrowing, that may affect the distribution of income; it is difficult to say in what direction. The basic and predominant determinant is marginal productivity: the continuous accumulation of capital depresses the rate of interest.

One type of earning that is not explained by the neoclassical theory of distribution is profit, a circumstance that is especially awkward because profits form a substantial part of national income (20–25 percent); they are an important incentive to production and risk taking as well as being an important source of funds for investment. The reason for the failure to explain profit lies in the essentially static character of the neoclassical theory and in its preoccupation with perfect competition. Under such assumptions, profit tends to disappear. In the real world, which is not static and where competition does not conform to the theoretical assumptions, profit may be explained by five causes. One is uncertainty. An essential characteristic of business enterprise is that not all future developments can be foreseen or insured against. Frank H. Knight (1921) introduced the distinction between risk, which can be insured for and thus treated as a regular cost of production, and uncertainty, which cannot. In a free enterprise economy, the willingness to cope with the uninsurable has to be remunerated, and thus it is a factor of production. A second way of accounting for profits is to explain them as a premium for introducing new technology or for producing more efficiently than one's competitors. This dynamic element in profits was stressed by Joseph Schumpeter (1911). In this view, prices are determined by the level of costs in the least progressive firms; the firm that introduces a new product or a new method will benefit from lower costs than its competitors. A third source of profits is monopoly and related forms of market power, whether deliberate as with cartels and other restrictive practices or arising from the industrial structure itself. Some economists have developed theories in which the main influence determining distributive shares is the relative "degree of monopoly" exerted by various factors of production, but this seems a bit one-sided. A fourth source of profits is sudden shifts in demand for a given product—so-called windfall profits, which may be accompanied by losses elsewhere. Finally, there are profits arising from general increases in total demand caused by a certain kind of inflationary process when costs, especially wages, lag behind rising prices. Such is not always the case in modern inflations.

Dynamic influences on distribution. *Prices.* Neoclassical theory throws light upon the long-run changes in distribution of income. It fails to take account of the short-run impact of business fluctuations, of inflation and deflation, of rapidly rising prices. This failure is an omission, though it is true that distributive shares do not fluctuate as much as employment, prices, and the state of business generally. This lagging in the behaviour of shares can be understood by remembering that they are determined by the quotient of the real remuneration of the factor and its productivity; both variables move, according to marginal productivity theory, in the same direction. Yet inflation and deflation do have a certain impact upon distribution: if purchasing power shrinks, profits are the first income category to suffer; next come wages, particularly through the effects of unemployment. In a depression, the recipients of fixed money incomes (such as interest and pensions) gain from lower prices. In an inflation the opposite happens.

How incomes are affected by changing conditions

The traditional inflationary sequence was that as prices rose, profits would increase, with wages lagging behind; this would tend to diminish the share of labour in the national income. Experience since World War II, however, has been different; in many countries wage levels tended to run ahead in the inflationary spiral and profits lagged behind, although most entrepreneurs eventually succeeded in shifting the burden of wage inflation onto the consumers. The result of the postwar inflation was a slight acceleration of the increase in the share of labour, while the shares of capital and land decreased faster than they would have in the absence of inflation. Profits as a whole held their own. The struggle among the various participants in the economic process no doubt added fuel to the inflationary fires.

Technology. Another dynamic influence is technological progress. The concept of the production function assumes a constant technology. But in reality the growth of production is much less the consequence of increased quantities of labour and capital than of improvements in their quality. This element in increased production is distributed in a way not fully explained by neoclassical theory. Part of the change in distribution that is caused by technological progress can be analyzed as resulting from changes in the elasticities of production. If $\frac{K}{Q} \cdot \frac{\partial Q}{\partial K}$ goes up, technological change is said to be "capital-using," and the share of capital will increase. This is what, in fact, may have happened; the change in technology has offset, though it has not neutralized, the decline in the share of capital caused by the employment of a higher amount of capital per worker. But another part of the fruits of technological progress is garnered by profit receivers, probably quite a substantial part. Businessmen who are quick innovators make high profits; in a rapidly changing society, profits tend to be high, a circumstance that is fortunate because profits are the mainspring of economic change. The high rate of growth experienced by the post-World War I Western world stemmed from this profit-innovation-profit nexus.

Personal income and neoclassical theory. The neoclassical theory endeavours to explain the prices of productive factors and the distributive shares received by them. It does not come to grips with a third category of distribution, that of personal income, which is much more affected by institutional arrangements and by characteristics of the social

structure. Profits in particular may be shared in various ways: they may accrue to stockholders, to workers, to management, or to the government; or they may be retained in the corporation. What happens depends on dividend policy, tax policy, and the existence of profit-sharing arrangements with workers. Neoclassical theory has little to say on these matters or on the fact that in present-day capitalist society the managers of big business are virtually in a position to fix their own personal incomes. Managers have so much power vis-à-vis the stockholders and their total share of profits is so relatively little that their ability to pay themselves high salaries is limited only by the conventions of the business world. These high incomes cannot be explained by the categories of the neoclassical theory, and they do not constitute an argument against the theory. They may well argue for changes in society's institutions, but that is a matter on which the neoclassical theory of distribution does not pontificate. A great deal of change could occur in the legal and social order without any disturbance to the theory. (J.P.)

Consumption

In economics the word consumption means the using up of goods and services. In modern economic terms it means, specifically, "final" consumption as distinguished from the using up of goods to produce other goods in a manufacturing industry. Final consumption must also be distinguished from the purchase by industry of fixed assets such as buildings and machinery, which is known as capital formation or investment. On the other hand, consumption expenditure by private persons is understood to include the purchase of durable goods, such as furniture or vehicles, as well as works of art that may increase in value over a period of time. The acquisition of such goods should actually be considered asset formation rather than consumption and should be classified with the acquisition of other assets such as houses, schools, roads, and hospitals.

Final consumption versus capital formation

In modern industrial economies, consumption as previously defined accounts for 70 or 80 percent of total national expenditure. Even in the Western capitalist countries a significant part of total consumption is determined directly by the expenditure of public authorities. Some of the benefits of this part of consumption, such as expenditure on defense or on public health, are widely diffused; others are directed by common consent to the benefit of particular sections of the community. These consist in part of specialized services such as education or medical care; but other services—such as unemployment compensation, state pensions for the elderly, and assistance to families deprived of the support of a wage earner—are designed to create greater equality in levels of consumption than would otherwise be obtained.

PATTERNS OF NATIONAL CONSUMPTION

The ways in which people spend their incomes show much uniformity among countries at the same economic level. Expenditure patterns in the United Kingdom, for example, are typical of western Europe. In 1949 the pattern was still affected by postwar shortages and rationing, but the level of total consumption was not very different from what it had been before the war. In the decades that followed, private consumption expenditure per person (measured at constant prices) doubled. In addition there was a great increase in public services such as health and education. Yet the broad distribution of expenditures remained strikingly constant in spite of the introduction of many new commodities and considerable changes in their relative prices. The percentage of total expenditure devoted to food fell, a phenomenon that usually accompanies a rising standard of living, and the largest proportionate increases were in the purchase and maintenance of private motor vehicles, of furniture and household goods, and of radio, television, and electrical goods. These three categories represent in part net additions to private wealth in the form of durable goods and also reflect the effect of technical progress. As in other industrial countries, much of the improvement in living standards has taken the form of more travel, better communication services, and the acquisition of labour-saving equipment.

Differences among countries

In most of the industrialized countries there has been a compound rate of increase in the total volume of consumption expenditure per person of 10 to 12 percent per year, the main exceptions to this being the United Kingdom and Japan, where consumption has grown at double this rate. But the pattern of change is similar in almost all countries. Food consumption has grown less rapidly than total consumption, particularly in the Scandinavian countries, Germany, and the countries of North America, where the rate of increase has been about 7 percent per year; expenditure on clothing has been growing at about the same rate as total consumption. Increases in rent outlays reflect higher energy costs in all of the industrialized countries. The acquisition of durable goods continues at a very high rate in all countries.

Comparable data on consumption in the poorer countries of the world are much harder to obtain and are usually less reliable, but it is probable that, expressed as a proportion of total consumption, food expenditure is about twice as important in much of Asia, Africa, and Latin America as it is in western Europe and North America. In the most economically advanced countries, food expenditure represents only one-quarter to one-third of the total, whereas in countries where the total expenditure per household is less than the equivalent of $1,500, the proportion rises to one-half or even greater. It should be noted that in the rural regions of poor countries the housing expenditure is minimal; in these areas shelter is rudimentary and largely self-provided.

Food consumption varies in character from country to country. This variation is due in part to climatic factors, and it also reflects differences in national food habits. The diet that is normally eaten in northern Europe and in Scandinavia is relatively low in fruit and vegetables but it contains a high proportion of milk, fats, and sugar. In France the consumption of vegetables and meat is relatively high. Fruit and vegetable consumption is generally high in southern Europe, while milk consumption in this area is low. In the Mediterranean countries food grains are generally preferred to potatoes and sugar as sources of carbohydrates.

But aside from these regional variations, the influence of general living standards is evident. The North American diet, for example, with its low grain and potato consumption and high consumption of sugar, meat, eggs, and fats is attributable more to a high standard of living than to any regional peculiarities of taste. These characteristics can be observed in the diets of the wealthier classes of most countries.

The influence of the general standard of living is also shown in the relative priorities that are accorded to the increased consumption of particular foods as incomes increase. These priorities are measured by economic statisticians in the form of income elasticities of expenditure, defined as the percentage increase in the consumption of an item divided by the percentage increase in income that makes the increased consumption possible. These elasticities are usually calculated for a given country by comparing the budgets of wealthy households with those of poor families. In countries such as the United States and Great Britain, the consumption of cereal foods actually decreases as incomes increase. In the less developed countries the elasticities are usually considerably higher, particularly for fruit and for products of animal origin. In these countries the consumption of carbohydrate foods is also increasing fairly rapidly as incomes rise.

THEORIES OF CONSUMER BEHAVIOUR

Factors influencing consumers. *Model of consumer behavior.* The theory and measurement of consumer behaviour forms an important part of modern economic theory. It was first developed during the 19th century on the basis of the following conceptions: that the purchase of any commodity gives the consumer a positive satisfaction or utility; the additional satisfaction derived from additional purchases of the same commodity declines as the consumer's supply of that commodity increases; and

with a given amount of money to spend, the consumer distributes the expenditure among commodities to maximize the total satisfaction or utility attainable from all those purchases. This rather crude model of consumer behaviour has undergone considerable refinement by modern mathematical economists. The advantage of this approach, which has had a strong and enduring effect on the theoretical and empirical work of economists, is that it separates the main economic variables influencing consumer behaviour—that is, income and prices—from all the remaining influences, such as individual preferences, social pressures, customs, and habits, but at the same time it unites them in a single analytical apparatus. Critics have often objected that the model assumes a rational person bent on scrupulously maximizing his satisfaction and that the model is thus part of a mechanistic stream of thought that has been substantially undermined by 20th-century advances in psychology. Still, the only useful criterion of any hypothesis is the range of situations in which the derivative model is shown validly to predict events. For example, it is useful to assume that the leaves of a tree attempt to maximize the amount of sunlight they receive, since the assumption implies that leaves are denser on the sunny side of trees than on the shady side, which can be checked from experience, or that billiard players make their shots as if they knew the mathematical formulas of mechanics. Similarly, to assume that consumers behave as if they were rational utility maximizers helps to provide accurate predictions of a broad range of market phenomena; *e.g.*, a fall in the price of a commodity will generally lead to increased consumption of that commodity, and an increase in consumer income will lead to increased consumption of most commodities. Only persistent discrepancies between predictions and events require a modification of the model's assumptions; some examples of such cases are discussed below.

Spending in relation to incomes

Income as determinant. The theory points to the income of consumers as the most important single determinant of their consumption patterns. It follows that in any community both the average income level and the distribution of incomes are important influences on total consumption. A community in which incomes are equally distributed consumes fewer luxury goods and fewer low-quality goods than one containing a few wealthy individuals and many poor people. Among wealthy people in early 19th-century England, a dinner with five main protein dishes—fish, meat, game, poultry, and ragout with truffles—was described as the minimum, while in poor years the families of agricultural labourers ate mainly oatmeal and potatoes; today the standardized produce of modern agriculture is part of most diets.

The classic model of consumers' behaviour implicitly assumes that the individual enjoys a constant income. In practice it may fluctuate according to the season, from year to year, or more generally over a lifetime. In the short run the consumption of some commodities is much affected by these income fluctuations, while the consumption of others is affected very little. Wage-earning households commonly have a weekly housekeeping allowance, out of which the necessities of food and clothing are bought, while the variable excess of earnings is spent on tobacco, alcoholic drinks, and entertainment. The expected average level of future income therefore influences consumption habits as much as actual present income, and commodities may be divided into two classes. The first consists of goods people buy when temporarily affluent but give up when temporarily poor, and the second consists of goods for which the pleasure of a temporarily higher level of consumption would not be worth the financial or psychological cost of giving them up in the future.

Consumers can also be influenced by their previous incomes. A person who owns an expensive car may continue to use it after his income falls, though at the lower level of income the individual would not choose to replace it with a similarly expensive vehicle in the long run. This may be a rational decision, in the sense that the value of the car in use may be greater than what it is worth in the second-hand automobile market; or it may be irrational, in the sense that an expensive habit that should have been abandoned is continued beyond the point where it can rationally be supported. The distinction is largely subjective and cannot be clearly made by an outside observer.

Over the life cycle as a whole, consumption patterns are markedly different in various occupations. In most of the unskilled or semiskilled occupations, the course of earnings is fairly stable: a young worker of 21 may earn as much as an older person. But in many of the professions an individual of 50 or 60 may earn many times the income of a person of 21; this gives the young wage earner a strong incentive to incur considerable debt with the expectation of amortizing it steadily throughout life, so that the typical consumption pattern of the occupation can be achieved earlier than otherwise. This applies particularly to such major purchases as houses, household furniture and equipment, and vehicles. Manual workers, on the other hand, whose expectations are little greater than their present consumption, generally prefer to rent living space rather than to own a house and are unwilling to raise their current consumption standards by incurring commitments of a longer term than that of ordinary installment credit.

Nonrational influences. To be fully rational and consistent, consumers need to have access to sufficient information on goods and their prices so that they can choose those with the lowest unit price for a given quality. But consumers do not always behave this way. Natural pearls are sold at a much higher price than cultured pearls, though the difference between them is demonstrable only by dissection or with X-rays, and their quality in use is identical. Brand-name drugs sell better and at higher prices than unbranded drugs that are manufactured from the same standard formula. To some extent this is due to what an American economist, Thorstein Veblen, called the desire for conspicuous consumption: part of the attraction of the good is simply its high price. It is also the result of consumers' ignorance, made more acute by the increasing sophistication of commodities whose qualities must be measured in many dimensions. If it is costly in time for the individual to become fully informed about the comparative qualities of competing products, it is not wholly irrational for the consumer to take the market price as an indicator of quality. The lack of information has given rise to consumers' organizations in most industrialized countries; these organizations test and report on a wide range of products for their subscribers.

Conspicuous consumption

The influence of modern advertising techniques must also be considered. Insofar as advertising informs the consumer of the range of alternatives, it can be argued that advertising merely increases the consumer's information; and insofar as advertising consciously or subconsciously changes consumer preferences, it remains one of the many factors determining consumer preferences that the economist takes as given. Advertising, however, cannot persuade the public to buy whatever the producer offers. Advertising is likely to be most effective in influencing consumers to choose one of several almost identical products being offered, such as toothpaste, cigarettes, or gasoline. But it may also raise the demand for the group of competing products as a whole. In addition, it can be argued that the total effect of modern advertising is to shift the preferences of consumers in favour of luxury goods rather than necessities, in favour of consumption rather than saving, and in favour of employment rather than leisure.

Attitudes toward necessities and luxuries. The distinction between necessities and luxuries is imprecise. The dividing line varies with the income and social class of the classifier and shifts as technology develops and as social values change. Only in the most undeveloped communities can necessities be defined purely in terms of physiological needs. Adam Smith wrote in 1776:

> By necessaries I understand not only the kind of commodities which are indispensably necessary for the support of life, but whatever the custom of the country renders it indecent for creditable people, even of the lowest order, to be without. . . . Under necessaries, therefore, I comprehend not only those things which nature, but those things which the established rules of decency have rendered necessary to the lowest rank

of people. All other things I call luxuries; without meaning by this appellation to throw the smallest degree of reproach upon the temperate use of them. Beer and ale, for example, in Great Britain, and wine, even in the wine countries, I call luxuries. A man of any rank may, without any reproach, abstain totally from tasting such liquors. Nature does not render them necessary for the support of life, and custom nowhere renders it indecent to live without them.

In the 19th century, with the development of more mathematical methods of reasoning based on a utilitarian calculus, the distinction came to be phrased differently. Necessities were defined as those commodities whose demand has an income elasticity less than unity, and luxuries as those with an income elasticity greater than unity. These definitions imply that as a worker's income increases the expenditure on necessities increases less than, and the expenditure on luxuries more than, proportionately. But even with the elasticity approach the distinction must vary over time. In 1950 the demand for television sets had a high income elasticity, whereas now, in some countries, television often is regarded as a necessity.

Changing attitudes toward luxury

Economists of the early 19th century all believed that the living standards of the working classes in capitalist societies would remain close to a subsistence level, meaning that luxuries would be more or less permanently denied them. But in modern industrialized economies even the poor consume goods that the early economists would not have considered necessary.

Role of luxuries. The historical and social role of luxury consumption is a subject of much interest. In the Mediterranean city-states during the Renaissance, the demand for luxuries provided a mainspring for the specialization of skilled labour and for the development of foreign travel and long-distance trade. The duke of Milan, Filippo Maria Visconti, possessed valuable English dogs, leopards from all parts of the East, and hunting birds from northern Europe. Some writers have argued that the luxurious consumption of the rich benefits the poor through the provision of employment opportunities that would not otherwise exist. A subtler version of this idea was proposed by Adam Smith, who contrasted the uselessness of menial labour employed by the rich for personal services with the benefits flowing from the employment of craftsmen who created luxurious products of enduring merit that eventually became available to society as a whole:

> The houses, the furniture, the clothing of the rich, in a little time, become useful to the inferior and middling ranks of people. . . . What was formerly a seat of the family of Seymour is now an inn upon the Bath road. The marriage-bed of James the First . . . was, a few years ago, the ornament of an ale-house at Dunfermline.

But Smith and most of the economists who succeeded him believed that, if the money spent on luxurious consumption by the rich was invested in useful production, society would benefit as a whole. The Industrial Revolution brought an increasing demand for funds for productive investment and made possible a more rapid rise in general standards of living than the world had known before. The classical economists thus argued that all luxury consumption involved a selfish diversion of labour and capital and acted as a brake on human progress.

This view was not seriously challenged until the English economist John Maynard Keynes published his *General Theory of Employment, Interest and Money* in 1935–36. Writing at a time when millions of workers were unemployed, Keynes argued that the consumption of luxuries was socially desirable if it provided jobs that would otherwise not exist. He also suggested that capitalism might be outrunning its investment opportunities, so that in the long run the problem of finding employment for capital itself would arise—a difficulty that might be postponed if the wealthy spent more on themselves:

> In so far as millionaires find their satisfaction in building mighty mansions to contain their bodies when alive and pyramids to shelter them after death, . . . the day when abundance of capital will interfere with abundance of output may be postponed.

In industrial countries since World War II, this pessimistic view has been overborne by a seemingly endless expansion in consumer industries. As fast as consumers accumulate durable goods, they become technologically or conventionally obsolete and are replaced by new goods. Instead of seeking more leisure, previously thought to be a main benefit of technical progress, the populations of the industrialized countries seem to prefer to work in order to buy more luxuries. To this extent the desire for leisure and the demand for luxuries are in direct competition.

Luxuries and leisure

Standards of consumption. In communist countries, public consumption has long been treated as more important than private luxury. In the last part of the 20th century this emphasis seemed to be giving way to the aim of catching up with the standards of consumption that prevail in capitalist countries. In the less developed countries of the Third World, the tension between the demand for luxuries and the low standard of living gives rise to acute economic and social problems. The rapid growth of international travel and communications since World War II has led the literate and skilled classes of every nation to seek similar standards of private consumption regardless of their national environment. This, in less developed countries, leads either to a highly unbalanced distribution of the national income or to the emigration of the skilled population. Thus the increasing awareness of the consumption habits of the most fortunate sections of the world's population is both a spur and a hindrance to general progress. (J.A.C.B.)

Economic fluctuations: stability and instability

BUSINESS CYCLES

Business cycles are best defined as fluctuations in the general level of economic activity, or more specifically, in the levels of employment, production, and prices. Figure 11 shows fluctuations in wholesale prices in four Western

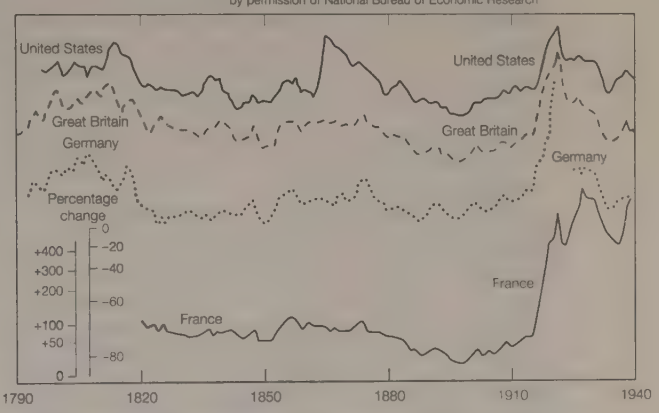

Figure 11: Wholesale price indexes for United States, Great Britain, Germany, and France, 1790–1940.

industrialized countries over the period from 1790 to 1940. Though some regularities in price movements are apparent, it is possible to ask whether the movements are regular enough to be called cycles.

The word *cycle* derives from the Greek word for circle. An object moving around a circle returns to its starting point; a wave motion, with upward and downward curves, may also be considered a cycle. The various movements characteristic of economic activity are not always as regular as waves, and for this reason some prefer to call them fluctuations.

The varieties of cycles

There are many types of economic fluctuations. Because of the complexity of economic phenomena, it may be that there are as many types of fluctuations or cycles as there are economic variables. There are daily cycles in commuter traffic or the consumption of electricity, to cite only two examples. Almost every aspect of economic life displays seasonal variations: sales of coal or ice, deposits in savings banks, monetary circulation, agricultural production, purchases of clothing, travel, housing, entertainment, and so on. As one lengthens the span of observation, one finds new kinds of fluctuations such as the hog cycle and

the wheat cycle, the inventory cycle, and the construction cycle. Finally, there are expansions or contractions of general economic activity that extend over periods of years.

Historical studies of cycles. Modern economic history has recorded a number of periods of difficult times, often called depressions, during which the business economy was marked by sudden stock market declines, commercial bankruptcies, bank failures, and mounting unemployment. Such crises were once looked upon as pathological incidents or catastrophes in economic life, rather than as a normal part of it. The notion of a "cycle" implies a different view. The following examples represent some of the attempts theorists have made to explain and predict business cycles.

Juglar's eight-year cycle. The first authority to explore economic cycles as periodically recurring phenomena was probably Clément Juglar, a French physician, in 1860. Other writers who developed Juglar's approach suggested that the cycles recur every nine or 10 years and distinguished three phases, or periods, of a typical cycle: prosperity, crisis, and liquidation. Subsequent analysis has tended to designate 1825, 1836, 1847, 1857, 1866, 1873, 1882, 1890, 1900, 1907, 1913, 1920, and 1929 as initial years of crisis. If that is correct, then the average interval between them was eight years, rather than nine or 10 as suggested by Juglar. In the years since 1929, the regularity of business fluctuations has been somewhat offset by government anticyclical policies and by increases in complexity and specialization that have reduced dependence on any one economic sector.

The wealth of data

The so-called Juglar cycle has often been regarded as the true, or major, economic cycle, but several smaller cycles have also been distinguished. Close study of the interval between the peaks of the Juglar cycle suggests that partial setbacks occur during the expansion, or upswing, and that there are partial recoveries during the contraction, or downswing. These smaller cycles generally coincide with changes in business inventories, lasting an average of 40 months. According to this analysis, other small cycles were said to result from changes in the demand for and supply of particular agricultural products such as hogs (three to four years), cotton (two years), and beef (five years in The Netherlands). Hide and leather production was thought to fluctuate in an 18-month cycle.

Kondratev's waves. Longer cycles have also been studied. The construction industry has been found to have cycles of 17 to 18 years in the United States and 20 to 22 years in England. Finally, there are the long waves, or so-called Kondratev cycles, named for a Russian economist, Nikolai D. Kondratev, who showed that in the major Western countries during the 150 years from 1790 to 1940 it was possible to distinguish three periods of slow expansions and contractions of economic activity averaging 50 years in length:

1. 1792–1850	Expansion: 1792–1815	23 years
	Contraction: 1815–50	35 years
2. 1850–96	Expansion: 1850–73	23 years
	Contraction: 1873–96	23 years
3. 1896–1940	Expansion: 1896–1920	24 years
	Contraction: 1920–40	20 years

Only these three Kondratev waves have been observed.

Some students of business cycles have analyzed them by statistical methods, in the hope of finding regularities that are not immediately apparent. One speculative theory has held that the larger cycles were built up from smaller ones. Thus, two seasonal cycles would produce a two-year cycle, two of which would produce a four-year cycle; two four-year cycles would become an eight-year, or Juglar, cycle, and so on. The hypothesis is not widely accepted.

Patterns of depressions and upswings. Cycles of varying lengths are closely bound up with economic growth. In 19th-century Germany, for example, upswings in total economic activity were associated with the growth of the railroad, metallurgy, textile, and building industries. Periodic crises brought slowdowns in growth. The crisis of 1873 led to a wave of financial and industrial bankruptcies; recovery started in 1877, when iron production ceased to fall, and by 1880 a new upswing was under way. The recession of 1882 was less severe than the previous one, but a slump that began in 1890 led to a serious depression, with complaints of overproduction.

Cycles in history

The year 1890 was also one of financial crisis in England and the United States. The British banking house of Baring Brothers failed, partly because of a revolution in Argentina. English pig-iron production fell from 8,300,000 tons in 1889 to 6,700,000 in 1892, and unemployment increased. That depression might have been less severe but for the international financial crisis, especially intense in the United States, where in 1893 a stock market panic led to widespread bank failures.

The recession of 1900 was followed by an unusually vigorous upsurge in almost all of the Western economies. U.S. pig-iron production increased by more than 150 percent during the expansion, which lasted until 1907; building permits more than doubled; and freight traffic rose by more than 50 percent. Prices rose more and more rapidly as the U.S. economy approached full employment.

Deviations from cycle patterns. Cycles are compounded of many elements. Historical fluctuations in economic activity cannot be explained entirely in terms of combinations of cycles and subcycles; there is always some factor left over, some element that does not fit the pattern of other fluctuations. It is possible, for example, to analyze a particular fluctuation into three principal components: a long component or trend; a very short, seasonal component; and an intermediate component, or Juglar cycle. But these components cannot be found exactly recombined in another fluctuation because of a residual element in the original fluctuation that does not have a cyclical form. If the residual is small, it might be attributed to errors of calculation or of measurement. Or, the residual might be regarded as the result of such accidental events as epidemics, floods, earthquakes, riots, strikes, revolutions, or wars, which obviously cannot be fitted into a recurring pattern. On a more sophisticated statistical level, it can be treated as "random movement." If the random element is always present, it becomes an essential element of the analysis to be dealt with in terms of probability.

For practical purposes, it would be useful to know the typical shape of a cycle and how to recognize its peak and trough. A great amount of work has been done in what may be called the morphology of cycles. In the United States, Arthur F. Burns and Wesley C. Mitchell have based such studies on the assumption that at any specific time there are as many cycles as there are forms of economic activity or variables to be studied and have tried to measure these in relation to a "reference cycle," which they artificially constructed as a standard of comparison. The object in such studies was to describe the shape of each specific cycle, to analyze its phases, to measure its duration and velocity, and to measure the amplitude or size of the cycle.

In studying various cycles, it has been possible to construct "lead and lag indicators"—that is, statistical series with cyclical turning points consistently leading or lagging behind the turns in general business activity. Researchers using these methods have identified a number of series, each of which reaches its turning point from two to 10 months before the turns in general business activity, and another group of series, which has followed the turns in business by two to seven months. Examples of leading series include published data for new business orders, residential building contracts, the stock market index, business failures, and the length of the average workweek. These and other leading indicators are widely used in economic forecasting.

Theories of economic fluctuation. A satisfactory explanation of cycles must isolate the forces and relationships that tend to produce these recurrent movements. There have been many theories of the business cycle. An understanding of them requires analysis of some of the factors that can cause cyclical movements. Theories of the business cycle, or, more properly, of economic fluctuations, may be classified in two groups: those that ascribe cyclical movements to external forces (exogenous factors) and those that attribute the fluctuations to internal forces (endogenous factors).

Keynesian theories. Some theorists examine the relationship between investment and consumption. According to Keynesian economists, any new expenditure—*e.g.,* on building a road or a factory—generates several times as much income as the expenditure itself. This occurs because those who are paid to build the road or factory will spend more of what they receive; their expenditures will thus become income for others, who will in their turn spend most of what they receive. Every new act of investment will, thus, have a stimulating effect on aggregate income. This relationship is known as the *investment multiplier.* Of itself, it cannot produce cyclical movements in the economy; it merely provides a positive impulse in an upward direction.

To the relationship between investment and consumption must be added that between consumer demand and investment. An increase in demand for refrigerators, for example, will eventually require increased investment in the facilities for producing them. This relationship is known as the *accelerator;* and it implies that an increase in national income will stimulate investment. As with the multiplier, it cannot of itself explain cyclical movements; it merely accounts for a fundamental instability.

It can be shown, however, that the multiplier and accelerator in combination may produce very strong cyclical movements. Thus, when an increase in investment occurs, it raises income by some larger amount, depending on the value of the multiplier. That increase in income may in turn induce a further increase in investment. The new investment will stimulate a further multiplier process, producing additional income and investment. In theory, the interaction might continue until a point is reached at which such resources as labour and capital are being fully utilized. At that point—with no increase in employment and, therefore, no rise in consumer demand—the operation of the accelerator would cease. That halt in demand, plus the lack of new capital, would cause new investment to decline and workers to be laid off. The process thus would go into reverse. The fluctuations in national income could take various forms, depending on the characteristics of the economy and the way in which the population allocated its income between consumption and savings. Such spending habits, of course, affect both the levels of consumer demand and capital investment. This theoretical analysis does not explain actual economic fluctuations; it is merely an aid to understanding them.

The analysis can be made more realistic by taking into account three other factors. First, since the theoretical, wide-swinging cycles engendered by the interaction of the multiplier and the accelerator are observed to occur only within narrow limits, one may assume that although the economy has an inherent tendency to swing very widely there are limits beyond which it cannot go. The upper limit to the swings would be the point at which full employment or full capacity is reached; the lower limit is more difficult to define, but it would be established when the forces that make for long-term economic growth begin to operate. Thus, the upswing of a cycle stops when it meets the upper limit; and the downswing stops at the lower limit, resulting in continuous cyclical movements with an overall upward trend—a pattern corresponding to the one found in history.

Upper and lower limits to swings

In economic life, there are many time lags: between the decision to invest and the completion of the project; between the farmer's decision to raise hogs and the arrival of pork chops at the store; between prices at the time of a decision and prices at the time the action is completed.

Random shocks, or what economists call exogenous factors, constitute the third type of phenomena affecting business cycles. These are such external disturbances to the system as weather changes, unexpected discoveries, political changes, wars, and so on. It is possible for such external impulses to cause cyclical motions within the system, in much the same way that striking a rocking horse with a stick will cause the horse to rock back and forth. The length of the cycle will be determined by the internal relationships of the system, but its intensity is governed by the external impulse.

Agricultural and climatic theories. Perhaps the oldest theories of the business cycle are those that link their cause to fluctuations of the harvest. Since crops depend upon natural factors that in turn may be affected by biological or meteorological cycles, such cycles will transmit their effects through the harvests to the rest of the economy. The 19th-century English economist William Stanley Jevons thought he had found the key to such a process in the behaviour of sunspots, which seemed to display a 10-year cycle. His naive explanation could not long withstand critical examination. It had a certain interest, however, in suggesting a causal factor that was completely detached from the economic system and one that could not be influenced by it in turn. Agricultural theories made sense at a time when agricultural goods represented 40 to 60 percent of the output of an advanced economy. By the turn of the 21st century, however, agriculture's contribution to an advanced economy's output might be 5 percent or less.

Psychological theories. A number of writers have explored mass psychology and its consequences for economic behaviour. Individuals are strongly influenced by the beliefs of the group or groups to which they belong. There are times when the general mood is optimistic, and others when it is pessimistic. An English economist, Arthur C. Pigou, in his *Industrial Fluctuations* (1927), put forward a theory of "noncompensated errors." He pointed out that if individuals behave in a completely autonomous way their errors in expectations will tend to offset each other. But if they imitate each other, their errors will accumulate until they acquire a global magnitude that may have powerful economic effects. This follow-the-crowd tendency obviously operates as a factor in the ups and downs of the stock exchanges, financial booms and crashes, and the behaviour of investors. One can say, however, that the psychological factor is not enough to explain economic fluctuations; moods of optimism and pessimism must themselves rest upon economic factors.

Political theories. Some observers have maintained that economic fluctuations result from political events. It is obvious that such events as the Napoleonic Wars, World Wars I and II, and even the Korean War of 1950–53 have had strong economic consequences. Even the imposition of a tax or an import restriction may have some dynamic effect upon the economy. In the United States, some economists have speculated that incumbent political leaders pressure the chairman of the Federal Reserve System to loosen monetary policy in advance of an election as a means of fostering prosperity. The question is whether such political factors are capable of producing cyclical movements.

Effects of wars and taxes

Technological theories. Ever since the Industrial Revolution at the end of the 18th century, technical innovations have followed each other without end but not without pause. There have been periods of innovation and quieter periods in which the innovations were being absorbed. More recently, computers and the Internet have influenced almost all aspects of economic production. It is possible that, if a rhythm could be found in these waves of change, the same rhythm might be responsible for corresponding movements in the economy. But it is equally possible that the technical innovations themselves have been dictated by the prior needs of the economy.

Demographic theories. Even population has been postulated as a cause of economic fluctuations. There are, undeniably, cyclical movements of population; it is possible to find fluctuations in the rates of marriage, birth, mortality, and migration; but the extent to which such fluctuations may have been caused by economic conditions is not clear.

Monetary theories. Some writers have ascribed economic fluctuations to the existence of money. Changes in the money supply do not always conform to underlying economic changes, and it is not difficult to see how this lack of coordination could produce disturbances in the economic system. Thus, an increase in the total quantity of money, if it is not matched by an increase in economic activity, will tend to produce higher prices; the higher prices may stimulate an investment boom, and so on.

The banking system, with its ability to expand the supply

of credit in a time of boom and to contract the supply of credit in time of recession, may in this way amplify small economic fluctuations into major cycles of prosperity and depression. Some theorists, such as Knut Wicksell, have emphasized the influence of the rate of interest: if the rate fixed by the banking system does not correspond to the "natural" rate dictated by the requirements of the economy, the disparity may of itself induce an expansion or contraction in economic activity.

Underconsumption theories. In a progressive economy, production tends to expand more rapidly than consumption. The disparity results from the unequal distribution of income; the rich do not consume all their income, while the poor do not have sufficient income to meet their consumption needs. This imbalance between output and sales has led to theories that the business cycle is caused by overproduction or underconsumption. But the basic, underlying cause is society's inadequate provision for an even flow of savings out of the excess of what is produced over what is consumed. In other words, saving is out of step with the requirements of the economy; it is improperly distributed over time.

Imbalance between output and sales

Investment theories. The fact that changes in the supply of savings, or loanable funds, are not closely coordinated with changes in the rest of the economy lies at the heart of the numerous theories that link investment imbalance to the business cycle. Savings accumulate when there is no immediate outlet for them in the form of new investment opportunities. When times become more favourable, these savings are invested in new industrial projects, and a wave of investment occurs that sweeps the rest of the economy along with it. It is in this context that the tools of analysis—the accelerator and the multiplier—find their application: the new investment creates new income, which in turn acts as a further stimulus to investment. An early observer of this phenomenon, a Russian economist, Mikhayl Tugan-Baranovsky, in 1894 published a study of industrial crises in England in which he maintained that the cycle of investment continues until all the capital funds have been used up. Bank credit expands as the cycle progresses. Disproportions then begin to develop among the various branches of production as well as between production in general and consumption. These imbalances lead to a new period of stagnation and depression.

Rational expectations and "real" business cycles. In the early 1970s, American economist Robert Lucas laid out what has come to be known as the "Lucas critique" of both Keynesian and monetarist theories of the business cycle. Such theories, he argued, ignored the effects of rational economic behaviour. Lucas observed that people do act rationally, for example, when they try to anticipate the consequences of a change in government policy. In some cases, their actions will offset the effects the government had hoped to achieve through the policy change.

Lucas won the 1995 Nobel Prize in Economic Science for development of the rational expectations theory. His work spurred other 20th-century economists who posited that business fluctuations are not due to changes in monetary policy; instead, these fluctuations stem from underlying changes in the economy. This came to be called real business cycle theory. In this view, economic fluctuations are not bad at all but, instead, are a healthy adjustment to underlying conditions—an adjustment that is necessary if economic growth is to continue. (H.Gu./Ed.)

STABILIZATION THEORIES AND POLICIES

The ultimate objective of research into the problems of economic instability (including fluctuations in output, employment, and prices) is to provide the foundation for stabilization policy—that is, for the systematic use of fiscal and monetary policies to improve an economy's performance. The main tasks, therefore, are to explain how levels of prices, output, and employment are determined and, on a more applied level, to furnish predictions of changes in these variables—predictions on which stabilization policy can be based.

Keynesian analysis. The problems of economic stability and instability have, naturally, been of concern to economists for a very long time. But, as a special field of investigation, it emerged most strongly from the confluence of two developments of the depression decade of the 1930s. One was the development of national income statistics; the other was the reorientation of theoretical thinking often referred to as the "Keynesian revolution."

To understand why the theoretical contributions of Keynes were regarded as so important through much of the 20th century, one must examine the workings of a modern economy. Such an economy comprises millions of people engaged in millions of distinct activities; these activities include the production, distribution, and consumption of all of the different goods and services that a modern economy provides. Some of the economic units are large, with hierarchies of executives and other managerial specialists who coordinate the productive activities of thousands or tens of thousands of people. Aside from these relatively small islands of preplanned and coordinated activity, most of the population pursues its myriad economic tasks without any overall supervised direction. It resembles an immensely complicated, continuously changing puzzle that is continually being solved and solved again through the market system. A breakdown in the coordination of activities, such as occurred in the depression decade of the 1930s, is very rare—in fact, it happened on that scale only once—or this system of organization would not survive. The way in which the economic puzzle is solved without anyone thinking about it has been the broad main theme of economic theory since the time of the English economist Adam Smith (1723–90).

The problem of coordination. If one singles out a particular household from the millions of economic units and studies it over a period of time, one can draw up a budget of that household's transactions. The budget will come out as a long list of amounts sold and amounts bought. If at any time this economic unit had tried to do something different from what it actually did (cutting down, say, on meat purchases to buy another pair of shoes), the solution of the economic puzzle would have been correspondingly different. At the prevailing prices the supply of meat would have exceeded the demand, and the demand for shoes would have exceeded the supply.

The price system; role of incentives

The point Keynes made, right or wrong, was that, if the economy were to function as a coordinated system, the activities of each economic unit must be somehow controlled—and controlled quite precisely. This is done through price incentives. By raising the price of a good (relative to the prices of everything else), any economic unit can, generally speaking, be made to demand less of it or to supply more of it; by lowering the price, it can be made to demand more or to supply less. Through the conflux of prices, an individual unit is thus led to fit its activities into the overall puzzle of market demands and supplies. If economic units could not be controlled in this fashion, the market-organized system could not possibly function.

Keynesians therefore believe that in any given situation there exists, theoretically, one and only one list of prices that will make the puzzle come out exactly right. But the amounts that economic units choose to supply or demand of various goods at any given price list depend on numerous factors, all of which change over time: the size of the population and labour force; the stock of material resources, technology, and labour skills; "tastes" for particular consumer goods; and attitudes toward consumption as against saving, toward leisure as against work, and so on. Government policies—tax rates, expenditures, welfare policies, money supply, the debt—also belong among the determinants of demand and supply. A change in any of these determinants will mean that the list of prices that previously would have equilibrated all of the different markets must be changed accordingly. If prices are "rigid," the system cannot adjust and coordination will break down.

Price flexibility. For coordination of activities to be preserved (or restored) when the economy is disturbed by changes in these determinants, something still more is required: each separate price must move in a direction that will restore equilibrium. This necessity for prices to adjust in certain directions may be expressed as a com-

munications requirement. To put it in somewhat extreme form: for a given economic unit to plan its activities so that they will "mesh" with those of others, it must have information about the intentions of everyone else in the system. When one of the determinants underlying market supplies and demands changes so as to disequilibrate the system, ensuing price movements must communicate the requisite information to everyone concerned.

One may suppose, for example, that in some period of political crisis the supply of crude oil from the Middle East is cut off. The immediate result will be a worldwide excess demand for oil and oil products of large proportions—that is, supply will fall far short of demand at going prices. At the same time, those who derive their income from Middle East oil production will have their incomes reduced, and excess supplies will emerge in the markets for the goods on which those incomes previously were spent. For the system to adjust, orders will have to go out to all demanders to cut down on their consumption of oil and for all other suppliers of oil to increase their output so that the gap between demand and supply can be closed. This is, in effect, what a rise in the world price of oil and oil products will accomplish—millions of gasoline and heating oil users the world over will respond to the pinch of higher prices, and the higher prices will also create a profit incentive for supply to be increased. (Falling prices will, in an analogous manner, close the gaps in the markets in which the initial disturbance caused excess supplies to develop.)

Prices that are not rigid for some institutional reason will move in response to excess demands and excess supplies. When demand exceeds supply, disappointed buyers will bid up the price; when supply exceeds demand, unsuccessful suppliers will bid it down. This mechanism solved the excess demand for the oil problem in the illustration above. The question, however, is whether throughout the system as a whole it will always act so as to move each of the prices toward its general equilibrium value.

Keynes said no. He maintained that there can be conditions under which excess demands (or supplies) will not be "effectively" communicated so that, although certain prices are at disequilibrium levels, no process of bidding them away from these inappropriate levels will get started. This is the flaw in the traditional conception of the operation of the price system that prompted Keynes to introduce the concept of "effective demand." To pre-Keynesian economists the implied distinction between "effective" and (presumably) "ineffective" demand would have had no analytical meaning. The logic of traditional economic theory suggested two possibilities that might make the price system inoperative: (1) that, in some markets, neither demanders nor suppliers respond to price incentives, so that a "gap" between demand and supply cannot be closed by price adjustments and (2) that, for various institutional reasons, prices in some markets are "rigid" and will not budge in response to the competitive pressures of excess demands or excess supplies. Keynes discovered a third possibility that, he argued, was responsible for the depth and duration of severe depressions: under certain conditions, some prices may show no tendency to change even though desires to buy and to sell do not coincide in the respective markets and even though no institutional reasons exist for the prices to be rigid.

Causes of depression

Say's Law. Many writers before Keynes raised the question of whether a capitalist economic system, relying as it did on the profit incentive to keep production going and maintain employment, was not in danger of running into depressed states from which the automatic workings of the price mechanism could not extricate it. But they tended to formulate the question in ways that allowed traditional economics to provide a demonstrable, reassuring answer. The answer is known in the economic literature as Say's Law of Markets, after the early 19th-century French economist Jean-Baptiste Say.

For western Europe, the 19th century was a period of rapid economic growth interrupted by several sharp and deep depressions. The growth was made possible in large measure by new modes of organizing production and new technologies, such as the spreading use of steam power. Was it possible that output might grow so great that there would not be a market for it all? Say's Law denied the possibility. "Supply creates its own demand," ran the answer. More precisely, the law asserted that the sum of all excess supplies, evaluated at market prices, must be identically equal to the sum of the market values of all excess demands. It could be neither more nor less. In the theoretical system of traditional economics, any inequality between these sums would quickly work itself out.

An important special case should be noted. The good in excess demand might, for instance, be money. One possibility, then, is excess supply for all the other goods, matched by an excess demand for money. A situation with excess demand for money matched by an excess supply of everything else is one in which the level of all money prices is too high relative to the existing stock of money. If this is the only trouble, however, Say's Law suggests a relatively simple remedy: increase the money supply to whatever extent required to eliminate the excess demand. The alternative is to wait for the deflation to work itself out. As the general level of prices declines, the "real" value of the money stock increases; this too, will, in the end, eliminate the excess demand for money.

Excess demand for money

Involuntary unemployment. Another possible cause of a general depression was suggested by Keynes. It may be approached in a highly simplified way by lumping all occupations together into one labour market and all goods and services together into a single commodity market. The aggregative system would thus include simply three goods: labour, commodities, and money. The Table provides a rough outline (a full treatment would be both technical and lengthy) of the development of a "Keynesian" depression.

Model of a "Keynesian" Depression

	Excess Demand (ED) or Excess Supply (ES) for:			notes
	labour	commodities	money	
Initial state	0	0	0	Equilibrium
State 2	0	ES_C	ED_M	$pES_C = ED_M$
State 3	ES_L	0	ED_M	$wES_L = ED_M$
State 4	ES_L	ED_C	0	$wES_L = ED_C$

One may begin by assuming (line 1) that the system is in full employment equilibrium—that is, prices and wages are at their equilibrium levels and there is no excess demand. Next the model may be put on the path to disaster by postulating either (1) some disturbance causing a shift of demand away from commodities and into money or (2) a reduction in the money supply. Either event will result in the situation described in the Table as State 2, but the one assumed is a reduction in the money supply by, say, 10 percent. The result is shown in the right-hand column of the Table, where the quantity of commodities supplied minus the quantity demanded multiplied by the price level (p) is equal in value to the excess demand for money.

If money wages and money prices could immediately be reduced in the same proportion (10 percent), output and employment could be maintained, and profits and wages would be unchanged in "real" terms. If money wages are initially inflexible, however, business firms cannot be induced to lower prices by 10 percent and maintain output. In this example they maintain prices in the neighbourhood of the initial price level—prices, then, are also "inflexible"—and deal with the excess supply by cutting back output and laying off workers. Reducing supply eliminates the excess supply of commodities by throwing the burden of excess supply back on the labour market. Thus, output and employment (which are "quantities") give way before prices do. This brings us to State 3 where, as in the Table, the excess supply of labour times the money wage rate (w) equals the excess demand for money in value.

If, with the system in this state, money wages do not give way and the money supply is not increased, the economy will remain at this level of unemployment indefinitely. One should recall that the only explanation for persistent unemployment that the pre-Keynesian economics had to offer was that money wages were "too high" relative to the money stock and tended to remain rigid at that level.

The lack of effective demand

Money wages might, nevertheless, give way so that, gradually, both wages and prices go down by 10 percent—that is to say, a reduction of the size that would have solved the entire problem had it occurred immediately (*before* unemployment could develop). This is shown in the last line of the Table, which represents (albeit crudely) what Keynes described as a state of "involuntary unemployment" and explained in terms of a failure of "effective demand."

In State 4, it is assumed, the excess demand for money is zero. Hence there is, at least temporarily, no tendency for money income either to fall further or to rise. The prevailing level of money income is too low to provide full employment. The excess supply of labour and the corresponding excess demand for commodities (of the same market value) show State 4 to be a disequilibrium state. The question is why the state tends to persist. Why is there no tendency for income and output to increase and to absorb the unemployment? Specifically, why does not the excess demand for commodities induce this expansion of output and absorption of unemployment?

Basically, the answer is that the unemployed do not have the cash (or the credit) to make the excess demand for commodities *effective*. The traditional economic theory would postulate that, when actual output is kept at a level below that of demand, competition between unsuccessful potential buyers would tend to raise prices, thereby stimulating an expansion. But this does not occur. The unemployed lack the means to engage in such bidding for the limited volume of output. The excess demand for commodities is not effective. It fails to produce the market signals that would induce adjustments of activities in the right direction. Business firms, on their side of the market, remain unwilling to hire from the pool of unemployed—even at low wages—because there is nothing to indicate that the resulting increment of output can actually be sold at remunerative prices.

Keynes called this "involuntary unemployment." It was not a happy choice of phrase since the term is neither self-explanatory nor very descriptive. Some earlier analysts of the unemployment problem had, however, tended to stress the kind of deadlock that might develop if workers held out for wages exceeding the market value of the product attributable to labour or if business firms insisted on trying to "exploit" labour by refusing to pay a wage corresponding to the value of labour's product. With the term "involuntary unemployment," Keynes wanted to emphasize that a thoroughly intractable unemployment situation could develop for which neither party was to blame in this sense. His theory envisaged a situation in which both parties were willing to cooperate, yet failed to get together. An effective demand failure might be described as "a failure to communicate."

The failure of the market system to communicate the necessary information arises because, in modern economies, money is the only means of payment. In offering their labour services, the unemployed will not demand payment in the form of the products of the individual firms. If they did, the excess demand for products would be effectively communicated to producers. The worker must have cash in order to exercise effective demand for goods. But to obtain the cash he must first succeed in selling his services.

When business begins to contract, the first manifestation is a decrease in investment that causes unemployment in the capital goods industries; the unemployed are deprived of the cash wage receipts required to make their consumption demands effective. Unemployment then spreads to consumer goods industries. In expansion, the opposite occurs: an increase in investment (or in government spending) leads to rehiring of workers out of the pool of unemployed. Re-employed workers will have the cash with which to exert effective demand. Hence business will pick up also in the consumer goods industries. Thus the theory suggests the use of fiscal policy (an increase in government spending or a decrease in taxes) to bring the economy out of an unemployment state that is due to a failure of effective demand.

Another observation may be made on Keynes's doctrine of effective demand. The fact that the persistence of unemployment will put pressure on wages also turns out to be a problem. The assumption in the foregoing discussion was that money wages were at the equilibrium level. Unemployment will tend to drive them down. Prices will tend to follow wages down, since declining money earnings for the employed will mean a declining volume of expenditures. In short, both wages and prices will tend to move away from, rather than toward, their "correct" equilibrium values. Once the economy has fallen into such a situation, Keynes pointed out, wage rigidity may actually be a blessing—a paradoxical conclusion from the standpoint of traditional economics.

National income accounting. *The circular flow of income and expenditure.* A proper understanding of income and expenditure theory requires some acquaintance with the concepts used in national income accounting. These accounts provide quantitative data on national income and national product. Reliable information on these was, for the most part, not available to economists working on problems of economic instability before the 1930s. Modern economics differs from earlier work most markedly in its quantitative, empirical orientation. The development of national income accounting made this possible.

The definitions of the major components of national income and product may, accordingly, be introduced in the course of explaining income and employment theory. The basic characteristic of the national income accounts is that they measure the level of economic activity in terms of both product supplied and of income generated. Correspondingly, national income analysis divides the economic system into distinct *sectors*. The simplest approach uses two sectors: a business sector and a household sector. All product is regarded as created by the business sector (thus, self-employed persons have to be treated as businesses in earning their income and as households in disposing of it). Final goods output is divided into two components: consumer goods produced for sale to households and investment goods for sale to firms. Similarly, all income is generated in the business sector and none of it in the household sector (nonmarket activities, such as the work of homemakers or home improvements, are not counted in national product and income). The level of income generated equals the market value of final goods output.

Economic sectors

Next is the household sector. All resources in the economy ultimately belong to households. The households, therefore, have claim to all of the income generated through the utilization of these resources by firms in creating the national product. Not all of the income is, however, actually paid out to households, since corporations retain part of their earnings. In building a simple model of the economy, one can disregard the "gross business saving" item of the national income accounts and deal with income as if it were all paid out (which means adopting the fiction that retained earnings are first paid out to shareholders who then reinvest the same amount in the same firms). The households, finally, dispose of their income in two ways: as expenditure on consumption goods and as saving.

The foregoing discussion has made two accounting statements involving income. First, income *generated* (Y) equals the value of consumption goods output (C^s) plus the value of investment goods output (I): $Y \equiv C^s + I$. Second, consumption goods expenditures (C^d) plus savings (S) equal income *disposal:* $Y \equiv C^d + S$. Both equalities hold simply because of the way that the variables are defined in the national income accounts. They hold true, moreover, whatever the actual level of income happens to be. Such equalities, which are true simply by definition, are called *identities* (and are marked as such by using the sign $\equiv$ instead of the usual equality sign). Another accounting convention may be noted here. Investment (I) is defined to include any discrepancy between consumer goods produced and consumer goods sold. If production exceeds sales, the unsold goods are part of inventory investment; if sales exceed output, inventory investment is negative, and I is reduced by the corresponding amount. It follows that C^s and C^d must be identically equal, so that it becomes unnecessary to distinguish between them by superscript. Since income generated is identically equal to income disposal, finally, it is clear that actual investment must always equal actual saving: $I \equiv S$. Investment is the value of additions to the system's stock of capital. Saving is the increase in the value of the household sector's wealth. For the system as a whole, the two must be equal.

Figure 12 shows the circular flow of income and expenditures connecting the two sectors. Investment and consumption expenditures add up to the *aggregate demand* for final goods output. The value of final goods output is paid out by the business sector as income to the household sector. The major part of income goes back to the business sector as expenditures on consumption goods; the remainder is allocated by households to saving. Corresponding to the counterclockwise money flow (but not shown) is the clockwise flow of the things that the money is paid for: labour and other resource services from households to firms in exchange for money income; consumer goods and services in exchange for consumption expenditures from firms to households; and equities, bonds, and other debt instruments issued by firms in return for the funds saved by households. Figure 12 shows a break in the flow of saving as it passes

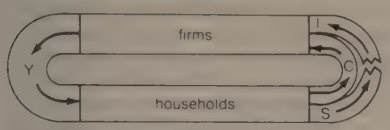

Figure 12: The circular flow of income expenditures (see text).

into investment. From the accounting standpoint—where investment necessarily equals saving—there is no rationale for this. It has been done here to focus attention on the point in the circular flow that, in the income–expenditure theory, represents the causal nexus in the income-determining process. This theory, in its simplest form, is the next topic.

A simple income–expenditure model. Because accounting identities—between gross national product and gross national income, between saving and investment, and so on—express relationships that must hold whatever the level of income, they cannot be used to explain what determines the particular level of income in a given period or what causes the level of income to change from one period to the next. The explanation of what happens must be based on statements about the behaviour of the participants in the economic system; in the present context, this means the behaviour of firms and households.

The dynamics of income and expenditure

The following oversimplified model of an economy assumes that the business sector will be satisfied to maintain *any* given level of output as long as *aggregate demand* (that is, expenditures on final goods) exactly equals the volume of income generated at that level of output. If, in a given period, aggregate demand exceeds the income payments made by firms in producing that period's output, firms will be expanding in the next period; if aggregate demand falls short of the income payments made, firms will contract in the next period. The naïveté of this supply hypothesis is evident from the fact that the behaviour of firms is described without any reference to the costs of their inputs or to the price of their outputs; the business sector passively adapts output and income generated to the level of aggregate demand. In this model, the level of income is entirely determined by aggregate demand. Firms will act so as to maintain that income flow if, and only if, the exact same amount that they pay out as incomes "comes back to them" in the form of spending on final goods output. If aggregate demand shrinks, production and employment will decline and there will be downward pressure on the price level; if aggregate demand swells, there will be an inflationary problem.

Leakages and injections

In the system of Figure 12, all of the income generated accrues to households. Households allocate their income to consumption and saving. With consumption there is no problem—it constitutes spending on final goods. Saving, however, does not constitute spending on final goods output. This part of the income generated by the business sector does not automatically come back to it in the form of revenue from sales. Saving, therefore, may be treated as a *leakage* from the circular flow.

Investment, which consists of spending of capital by the business sector on new plant and equipment and on desired additions to inventories, is, in the same terminology, an *injection* into the circular flow. If, for example, investment and saving each amount to $20,000,000 per year, the leakage and the injection will balance. But if saving is $20,000,000 per year and the injection of investment expenditures is only $10,000,000 per year, there will be a disequilibrium. Unsold goods will accumulate at an annual rate of $10,000,000. The business sector, however, will not rest content with this state of affairs but will act to reduce output, employment, and (perhaps) prices. Households will be forced to reduce their consumption spending. The reduction of income will go on until the planned (or desired) rates of saving and investment become equal. A similar argument will show that, if the leakage of planned saving were to fall short of the injection of planned investment, the level of income would rise.

When income is at a level such that there is no ongoing tendency for it to change in either direction, the system is in "income equilibrium." The simple system depicted in Figure 12 is in income equilibrium when the condition shown by this equation is fulfilled: $I = S$. This is not, however, the accounting identity discussed earlier. The symbols I and S now refer to planned, or desired, magnitudes, which may very well be unequal. When planned investment exceeds planned saving, income will be rising. When planned saving exceeds planned investment, income will be falling. An equivalent way of stating the above "equilibrium condition" is to write $Y = C + I$. In this equation the left-hand side is actual income and the right-hand side is planned aggregate demand.

This is the simplest class of income-determination model. It makes no allowance for international trade or government economic activity. Those may be treated in the same way that saving and investment were treated—as leakages or injections. Thus exports constitute spending by foreign nationals on domestic goods—an injection. Imports constitute spending out of domestic income on foreign goods—a leakage. Taxes are taken out of the circular flow—a leakage—whereas government expenditures are an injection. The effects of these leakages and injections on the level of income are analogous to those of saving and investment. If income is initially at an equilibrium level, an increase in a leakage (if not at the same time offset by a decrease in another leakage or an increase in an injection) will cause income to fall. An increase in an injection (not offset by a decrease in another injection or an increase in a leakage) will cause income to rise. An income equilibrium is reached when the sum of all leakages is balanced by the sum of all injections.

The multiplier

The simple income–expenditure model of the economy is not a complete model. It suffices to show only the *direction* of the change in income that would result from, say, a decline in planned investment (or a rise in taxes or a decline of exports). It does not show the *extent* of the income change.

To do this the model must be expanded to include a description of how consumers spend their incomes. For the sake of the exposition, one may assume that the spending of households varies according to the size of their incomes. A simple way of putting this is the following equation: $C = a + by$. In this equation the coefficient a is a constant indicating the amount that households will spend on consumption independently of the level of income received in the current period, and the coefficient b gives the fraction of each dollar of income that will be spent on consumption goods.

If one were able to obtain reliable quantitative information on the volume of investment spending being planned and on the coefficients a and b of the "consumption function" above, one could then calculate the value of aggregate demand $(C + I)$ for every possible level of income Y. Only one of these alternative levels of income is an equilibrium one; that is, one for which aggregate demand will ensure that all of the income paid out by firms "comes back" to the business sector as spending on final goods. The equilibrium condition is: $Y = C + I$.

Figure 13 shows how the level of income in the system is determined, on the assumption that investment is $20,000,000, that the coefficient a is $20,000,000, and that the coefficient b (the fraction of each dollar of income that consumers will spend) is 0.6. The horizontal axis measures income, the vertical, aggregate demand $(C + I)$. The line drawn at a 45° angle (from 0) contains all of the points at

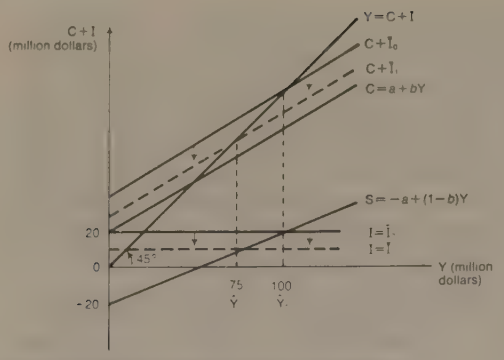

Figure 13: Relation between income and aggregate demand (see text).

which *suppliers* might be in equilibrium; *i.e.*, the points in the space at which aggregate demand would have the same value as income. The investment schedule (marked $I = \bar{I}_0$) is drawn parallel to the income axis at height 20, showing that investment spending does not depend on income. The consumption function (marked $C = a + by$) starts at 20 on the vertical axis (the value of a) and rises 60 cents for each dollar of income (the value of b) to the right. The aggregate demand schedule (marked $C + \bar{I}_0$) is obtained by the vertical summation of the C and $\bar{I}_0$ schedules. It contains all of the points at which *demanders* would be in equilibrium, showing, for each level of income, the volume of spending on final goods that they would be satisfied to maintain.

The only position that demanders and suppliers will both be satisfied to maintain is given by the intersection of the aggregate demand schedule with the 45° line. In Figure 13 this point ($\hat{Y}_0$) is found at an income level of $100,000,000. For this simple system, which has but one leakage and one injection, the equilibrium level of income may equally well be regarded as determined by the condition that planned saving equals planned investment. Since saving is defined as household income not spent on consumption (*i.e.*, $Y - C \equiv S$), one obtains (by substituting $a + by$ for c) the saving schedules $S = -a + (1 - b)\,Y$, which in Figure 13 is shown to intersect the investment schedule at $Y = \$100,000,000$.

Figure 13 shows what will happen if this equilibrium is disturbed. Consider a (temporary) situation in which income is running at *more than* $100,000,000 per year. At all levels of income to the right of $\hat{Y}_0$ aggregate demand ($C + \bar{I}_0$) is seen to fall below supply as given by the 45° line. (Also, saving exceeds investment.) The business sector will not be willing to maintain this state of affairs but will contract. *An excess supply of final goods is associated with falling income.* Similarly, at income levels to the left of $\hat{Y}_0$, where investment exceeds saving, aggregate demand will exceed supply. *An excess demand for final goods is associated with rising income.*

Finally, Figure 13 shows how much income would fall as a result of a decline in investment by $10,000,000 per year (*cf.* the dotted lines). The decline in investment is shown by the shift of the investment schedule from $\bar{I}_0$ to $\bar{I}_1$, which results in a downward shift of the aggregate demand schedule from $C + \bar{I}_0$ to $C + \bar{I}_1$. The new income equilibrium ($\hat{Y}_1$) is found at $Y = \$75,000,000$.

Thus a change in investment spending (ΔI) of $10,000,000 is found to lead to a change in income (ΔY) of a larger amount, here $25,000,000, which is to say, by a multiple of 2.5. The reason is that, when the $10,000,000 is transmitted to households as income, households will increase their consumption spending by $6,000,000 ($b \times \$10,000,000$). This rise in consumption spending again raises income, and of this additional income 60 percent is also spent on consumption—and so on. Each time, 40 percent of the increment to income "leaks" into saving. The relationship between the initial change in "autonomous spending" (ΔI) and the change in the level of income (ΔY), which will have taken place once this process has run its course, is given by:

$$\Delta Y = \left(\frac{1}{1-b}\right)\Delta I$$

where, following Keynes, the expression $\left(\frac{1}{1-b}\right)$ is called the "Multiplier."

Stabilization policy

The model of income determination presented above is exceedingly simple; it captures little of the complexity of a modern industrialized economy. It does, however, suggest one approach to the problem of stabilizing the economy at a high level of income and employment. Assuming that the consumption function is fairly stable (*i.e.*, that the level of consumption spending associated with any level of income can, with a fair degree of accuracy, be predicted on the basis of past experience), fluctuations in income may be attributed to changes in the other variables. Historical statistics show investment spending by private business to have been the most volatile of the major components of national income; changes in investment, therefore, tend (as in the example above) to be the focus of concern for one school of economists. The implication is that the government can manipulate "injections" and "leakages" so as to offset changes in private investment. Thus a drop in investment might be offset by a corresponding increase in government expenditures (increasing an injection) or a decrease in taxes (decreasing a leakage). These measures belong to fiscal policy.

Monetary policy. Another point of view holds that the fiscal approach presented above is misleading because it ignores the part played by monetary factors in determining the level of economic activity. The following discussion presents an alternative model, which, though equally simplistic, suggests that primary reliance be put on monetary policy.

"Money" in what follows may be taken to refer to currency (coins and notes) plus the checking deposit liabilities of commercial banks. For the sake of brevity, the model developed in the preceding section will be referred to as the income model. The naive quantity theory model that will be explained here may be labelled the money model.

The dynamics of income and money

The income model dealt with changes in money income in terms of the demand for and supply of output. The money model focusses on the supply of and demand for money. The income model explained the determination of the level of income in terms of relationships between its component flows. The money model emphasizes the relationship between money supply and income. The structure of the income model was based on the distinction between household and business (and government) sectors. In the money model, the distinction is between the banking sector (supplying the money) and the nonbanking sectors (the demanders). The concept of income is the same in both models.

In the money model, the supply of money is treated with the same simplicity that was accorded investment in the income model—as "autonomously" determined, which is to say that it is not affected by other factors: $M^s = \bar{M}$. This assumes that the central bank is able completely to control the stock of money, which is held at whatever level the bank desires.

The dynamic relationship in the income model was the consumption function. Here it is the money demand function. The amount of money demanded is assumed to vary with income (and, in this naive version of quantity theory, with nothing else). The simplest relationship between income and the demand for money would be: $M^d = kY$. Here, k is a constant. Since Y is a flow (measured per year) and M^d a stock (the average stock of money over the year), k has the dimension of a "storage period." If $k = 1/4$, for example, the equation states that the nonbanking public desires on the average to hold a cash balance that is equal to the total of three months' income.

Since there is a determined amount of money in the system, it can be in equilibrium only when the nonbanking sector is satisfied to hold exactly the amount of money that exists, no more and no less: $M^d = M^s$. The system represented by these three equations is shown in Figure 14. The determination of income in the system is shown by assuming $M^s = \$25,000,000$ and $k = 1/4$. The amount of money demanded is equal to supply when income is $100,000,000. A reduction of the money supply to $20,000,000 will cause income to decline to a level of $80,000,000 per year.

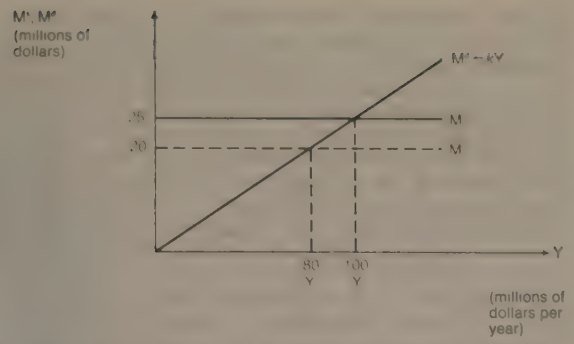

Figure 14: Relation between money demand and income (see text).

Changes in cash balances

Figure 14 shows what will happen if income temporarily exceeds the figure of $100,000,000 per year. To the right of $\hat{Y}_0$, the amount of money demanded exceeds the existing stock of it. The way for an individual to build up his cash balance is to reduce his disbursements below his receipts. But his spending (to the extent that it is spending on final goods at least) is somebody else's income. A general attempt to build up cash balances cannot succeed—it does not induce an increase in the money supply in this model—because it will result in a decline of income throughout the system. This decline will continue to whatever level is required to make the nonbanking sector bring the amount of money it demands into line with the amount in existence. *An excess demand for money is associated with falling income.* Similarly, if the amount of money demanded falls short of the amount supplied, an individual may decide to reduce his cash balance by increasing his disbursements—but the money stays in the system; incomes will rise all around. *An excess supply of money is associated with rising income.*

The stabilization policy that this model suggests is obvious: if the relationship between income and the demand for money is stable, the system can be maintained in equilibrium by keeping the money supply constant or, in a growing economy, by allowing the money stock to grow at roughly the same rate as real output. If the relationship between income and the demand for money is found to shift about over time, the money stock should be made to grow more rapidly in periods of increasing demand for money and more slowly in periods of decreasing demand.

Comparisons of the income and money models. Although the two models seem to have nothing in common—the crucial variables of one do not even appear in the other—their descriptions of what happens during income level movements are not contradictory. Falling income is associated with an excess supply of goods and services in the income model, with an excess demand for money in the money model. Rising income is associated with an excess demand for goods in the first model, with an excess supply of money in the other. Evidently the two models give only *partial* descriptions of what is going on: one model looks at the process from the "real" side only and the other from the "monetary" side. But an excess demand for goods on one side will be associated with an excess supply of moneyon the other, and vice versa, so in this respect the two are consistent.

The controversy between the two schools of thought represented by the models has mainly to do with two issues. One issue is which set of policy instruments—fiscal or monetary—provides the best means of stabilizing the economy. The other, more fundamental, issue concerns the causes of income movements. As seen above, changes in investment were the main cause of income movements in the income model; changes in the money stock were the main cause in the money model. Simplistic as the two models are, they embody the conflicting hypotheses of the two contending schools. Income–expenditure theorists attribute the instability of income primarily to events that influence the business sector's expectations with regard to the profitability of new investment, thus influencing investment. The modern quantity theorists see the irregular time path of the money stock as the most important factor.

The gross features of economic history do not contradict either hypothesis. Private investment has indeed been the most volatile component of Gross National Product. Similarly, the movements of the money stock have conformed to those of money income: rapid inflation has been associated with a rapid growth of the money supply; severe recessions, with a decline in the money supply; and mild recessions, with a slowdown in the growth of the money supply. ("Mild" recessions may be thought of as recessions during which total employment stagnates, and the growth in unemployment, therefore, is largely due to the growth of the labour force.) The controversy has in large measure come to concern the *direction of causation:* one side maintains that shifts in investment cause income changes and infers that these in turn induce changes in the money stock which go in the same direction; the other side maintains that changes in the size or rate of growth of the money stock cause income changes that in turn will tend to fall most heavily on the investment component of income.

The question of causation

The problem of resolving this controversy is twofold. First, the theoretical issue is less clear-cut than implied above. Each side acknowledges that neither investment nor the money supply is autonomous and that each affects the other. The question has become, therefore, which model is "most nearly true" and which model, consequently, should be regarded as a "first approximation" in guiding stabilization policy.

Second, the empirical methods at the disposal of economists are not yet adequate for settling such issues. Attempts have been made to compare the performance of the two models by testing whether the best predictions of income are obtained by using actual data for "autonomous expenditures" and assuming that consumption will obey the consumption–income relation that has generally obtained in the past or by using actual money stock figures and assuming that money demand will obey the relation to income that has generally obtained in the past. These attempts have bogged down in disagreements on various statistical matters and must be judged inconclusive. They have shown, however, that even with consumption functions and money demand functions that are a good deal more "reasonable" than the naive relationships above, the predictions of both models are too inaccurate for the purposes of stabilization policy.

Each model emphasizes one set of disturbances ("real" or "monetary", respectively) that will cause income to change. Each gives a partial view of the process of income-level movements. What is needed, therefore, is a third model explaining the linkages between "real" and "monetary" forces that these two simple models leave out.

Interest-rate policy. The third model brings a crucially important—but hitherto generally neglected—element into the picture of the economic system; namely, financial markets. For simplicity, the model has only one financial market; there is only one class of financial instruments (referred to as "securities") and only one yield (a single interest rate). The standard security may be thought of as a bond promising to pay annually a fixed number of dollars. The interest rate is the value of the coupon expressed as a percentage of the market price of the bond. Consequently, if excess demand for bonds brings their price up, the interest rate falls; if excess supply sends the bond price down, the interest rate rises.

Role of financial markets

The working of the financial market is depicted in the model as follows. Investment by the business sector is assumed to be financed through the issue of securities. The higher the interest rate that firms must pay on their securities, the smaller will be the investment program that they see as promising to be profitable. Thus investment will be discouraged by a rise and encouraged by a fall in the interest rate. Households, in deciding how to divide their income between consumption and saving, will consider the amount of future consumption that can be gained by abstaining from consumption now (*i.e.*, by saving). The higher the rate of interest, the larger the amount that can be spent on future consumption per dollar not spent in the present. Thus saving is encouraged by a rise and discouraged by a fall in the interest rate. Coins, notes, and some checking deposits are assets on which interest is not

paid. An individual who holds them has the alternative of converting some part of his money holdings into interest-bearing form. Thus the amount of money demanded will tend to diminish when the interest rate rises and to increase when it falls. The banking system creates money by buying assets from the public, paying for the assets through the issuance of additional monetary liabilities (*e.g.*, checking deposits). Banks must decide whether turning part of their cash reserves to an income-earning use is worth the risks of decreased "liquidity" entailed by lower bank reserves. Hence there is a tendency for the money supply to increase when the interest rate rises and to decrease when it falls.

Interest rate as price

In this model, then, the interest rate acts as a price in controlling the behaviour of the individual agents whose activities are to be coordinated. The interest rate itself is determined by the demand for and supply of money and securities. An increase in planned investment will be associated with the issuance of a large volume of securities. It will tend, therefore, to create an excess supply of securities, to lower securities prices, and to raise the rate of interest. Similarly, an increase in planned saving will tend to create an excess demand for securities, to raise their prices, and to lower the rate of interest. An increased demand for money will, in part, reduce the demand for and increase the supply of securities; it tends to create an excess supply of securities and to raise the interest rate. An increase in the supply of money will tend to reduce the rate of interest.

These qualitative propositions are the framework of the new model, integrating the two previous models as follows: (1) $I = I(r)$; (2) $C = C(Y,r)$; (3) $S = Y - C$; (4) $S = I$; (5) $M^d = M^d(Y,r)$; (6) $M^s = M^s(r)$; and (7) $M^d = M^s$. Here, Equations 1 through 4 restate the income model with the modification that investment is no longer simply "autonomous" but depends on the current level of the interest rate (r). Equations 5 through 7 restate the money model with the modification that the demand for money and the supply of money also depend on the interest rate. Two conditions now have to be simultaneously fulfilled for the system to be in equilibrium: desired saving must equal desired investment (Equation 4), and the amount of money that individuals and firms desire to hold must equal the amount that the banking sector desires to supply (Equation 7).

Only a partial account of the ways in which this model works can be given here. The following illustrative examples begin with the system in equilibrium at full employment. The first illustration adopts the view of someone who has learned the income model and hence is thoroughly imbued with the idea that rising income results from an excess of planned investment over planned saving. Faced with the proposition, drawn from the money model, that an increase in the money supply will also cause income to rise, he will ask how such a change in the money supply can cause a discrepancy between saving and investment when there was none to begin with. The answer is that an increase in M^s will mean that there is an excess supply of money and a corresponding excess demand for commodities and securities, but the *immediate* impact of excess demand will be felt almost exclusively in the securities market. The excess demand for securities drives the rate of interest down—and this encourages investment and discourages saving. At that point, consequently, a "gap" opens up between desired saving and investment.

For the second illustration, consider instead someone who has learned the money model and who, consequently, knows that income falls when the amount of money demanded exceeds the supply. In Keynes's work the "disturbance" given the most play is some unspecified event that makes business firms take a darker view of the returns to be expected from new investment. Hence, the amount of investment that they will want to undertake at the prevailing interest rate declines. The question is how such a change in planned investment can cause a discrepancy between money demand and money supply when there was none to begin with. The simplest answer is that a decline in planned investment will be associated with a reduction in the amount of securities floated on the market and thus with the emergence of an excess demand for securities. This drives securities prices up, which is to say that the interest rate falls. At a lower rate of interest, individuals will desire larger money balances than before; in addition, the banks will tend to reduce the money stock somewhat. At that point, consequently, a gap will open between the amount of money demanded and the amount supplied.

Government fiscal policy

The analysis of the consequences of government fiscal action is somewhat more complicated. If the government tries to stimulate the economy through increased expenditures, the effects will be felt in at least two ways. First, the increased spending is an "injection" added to commodity demand and may be treated, therefore, from the Model A standpoint in the same way as an increase in private investment. Second, however, this spending may be financed through increased taxes, through government borrowing, through creation of new money, or through some combination of the three. The strongest effects are gained by following the third alternative, the creation of new money. The excess demand for goods and services created by the increase in spending will then be matched by an excess supply of money, which, as seen above, will drive down the interest rate and cause increased investment, etc. To the direct stimulus of the spending program, this method of paying for it adds the indirectly achieved stimulus of increased private investment. (Needless to say, the double effect on money income is not always desirable. The fact that this method of financing government spending has almost always been heavily resorted to in wartime accounts for the historical association of large inflations with wars.) The method of the second alternative, government borrowing, consists of financing the increase in spending through the issue of government bonds. This creates an excess supply of securities, driving up the interest rate. At the higher interest rate, money demand is lessened and money supply somewhat increased, but the consequent excess supply of money will be of smaller magnitude than that entailed by creating new money. The higher interest rate will also discourage private investment. Thus the indirect effects of government borrowing are seen to involve a decrease in private investment partially offsetting the initial increase in government spending. The size of this offset has become one of the major issues between "monetarist" and "income–expenditure" economists. The monetarists argue that the offset is so nearly complete that fiscal action will be largely ineffectual unless it is accompanied by an increase in the money supply, but an increase in the money supply will have almost as powerful effects without any simultaneous fiscal action. The other side concedes that fiscal action will be more powerful when financed through changes in the money supply but maintains that countercyclical variations in government spending financed through borrowing must still be regarded as an important stabilization method.

The "natural" rate of interest and effective demand. *The thought of Knut Wicksell.* Around the turn of the century, the Swedish economist Knut Wicksell contributed greatly to the understanding of the function of the rate of interest in the mechanism determining income and price-level movements. Assuming an economy initially in full-employment equilibrium, Wicksell analyzed the various ways in which the system might depart from that position because of discrepancies between the prevailing market rate of interest and what he termed the "natural rate." The latter rate, hypothetical rather than directly observable, may be thought of as the interest rate level that would have to prevail for the system to remain at full employment with stable prices. In illustrating the use made of this concept, one should distinguish between processes initiated by "real" disturbances (the first two examples below) and those initiated by "monetary" disturbances (the third example).

The first example is one in which business firms see increased opportunities for profitable investment. The system is already at full employment, and hence an increase in spending on investment without a corresponding decrease in spending for consumption would spell inflation. What kind of adjustment will maintain stable prices? A rise in the interest rate will (1) moderate the increase in

investment spending and (2) cause households to divert some of their income from consumption into increased saving. The hypothetical level of the interest rate that will exactly match the net increase in investment with the decrease in consumption (increase in saving) is the new value of Wicksell's "natural rate." But the adjustment of the market rate may, for several reasons, come to a halt after going only part of the way to the new natural rate level. At some level of the market rate below natural rate, where planned investment still exceeds the savings that households provide for its financing, the banks may step in and finance the difference through expansion of the money supply. Thus inflation results. In Wicksell's theory there is inflationary pressure on the system associated with a market rate below the natural level and, in the version of it given here, with an increase in the money supply.

Inflationary response to the interest rate

The second example involves a change in public behaviour in that households desire to save more and consume less, out of any given level of income. The decreased demand for consumption goods threatens to cause deflation (or unemployment). To prevent this it is necessary to switch resources over to investment goods production, which requires a lowering of the interest rate. Thus an increase in saving means that the natural rate of interest declines. The adjustment of the market rate of interest may again be incomplete if falling rates induce banks, say, to reduce their new lending below scheduled loan repayments, thus reducing the money supply. Part of the saving done by households then goes, directly or indirectly, into reducing the private sector's indebtedness to banks rather than into financing investment. Thus deflationary pressure on the system is, in Wicksell's theory, associated with a market rate of interest above the natural rate and, in this example, with a decreased supply of money.

The third example is one in which banks desire to expand their loans and, thereby, their monetary liabilities—creating a "monetary" disturbance. Since "real" incentives to save and to invest have not changed, the natural rate of interest has not changed. The increased supply of bank credit will, however, drive the market rate down. It goes below the natural rate, the money supply is increased in the process, and inflation is the result.

Keynes and Wicksell. Keynes first took up Wicksell's idea in his *Treatise on Money* (1930). In Wicksell's writings, discrepancies between the natural and market rates had invariably been associated with expansion or contraction of bank credit. Keynes emphasized that such discrepancies may develop and continue without expansion or contraction of the money supply, because of speculation in the securities markets. For example, if the natural rate has decreased and the market rate starts to edge down in response to an excess of the household savings offered in demand for securities over the supply of new securities marketed to finance investment, securities prices will rise. This, Keynes suggested, will cause some speculators in "old" securities to enter the market and supply savers with securities from their holdings. The excess demand pressure on the market is thus relieved and the rise in prices (fall of the market rate) halted. The motive for these transactions is the speculators' hope that they can buy back their securities at lower prices later. In the meantime, the speculators hold their funds in the form of ready money; there has been an increase in the amount of money demanded rather than, as Wicksell assumed, a decrease in the money supply.

The Wicksell–Keynes theory was an important contribution to the theory of the income-determination process. Yet there is nothing in its main elements that should have startled a pre-Wicksellian traditional economist. The natural rate is essentially the interest rate that would prevail in general equilibrium, and a market rate different from the natural rate is a disequilibrium interest rate. Traditional economics was clear enough as to the consequences that will follow if one or more of the prices in the system "gets stuck" at a disequilibrium level. The Wicksell–Keynes theory, therefore, may be regarded as a particular application of previously familiar principles.

Keynes returned to the Wicksellian theme in *The General Theory of Employment, Interest and Money* (1936), but in that revolutionary work he gave the theory a genuinely novel twist: he argued that the system might be seriously out of equilibrium even though the prevailing interest rate was exactly at the Wicksellian natural level. This might happen because the interest rate mechanism cannot ensure that the plans of households and business firms with regard to future consumption and production will mesh with each other. There might, for example, be an increase in household saving—that is, a decrease in the demand for current consumption goods and an increase in the planned demand for future goods. Coordination of household and business activities requires that business firms respond by shifting resources out of the production of present consumption goods and into investment activities that lay the groundwork for increased output in the future. Households, in carrying out their saving decisions, do not place contractual orders with producers for future deliveries of particular goods and services. Thus the future demands implicit in current saving decisions may not be effectively communicated to producers, as efficient coordination would require. If producers draw up their investment plans on the basis of forecasts of future demand that do not correspond to the spending that households are prepared to undertake in the future, there will be an excess demand (or excess supply) for future output.

Coordination of consumer and producer planning

Such effective demand failure is not the result of changes in interest rates or in the supply of money. The logical way of dealing with it—when it occurs—is through fiscal policy measures. The effective demand doctrine is the signal contribution of Keynesian economics to income and employment theory. It is thus no coincidence that Keynesian economics has become associated with an emphasis on the use of fiscal, rather than monetary, stabilization policies.

BIBLIOGRAPHY

General works. Comprehensive resources include JOHN EATWELL, MURRAY MILGATE, and PETER NEWMAN (eds.), *The New Palgrave: A Dictionary of Economics,* 4 vol. (1987); and DOUGLAS GREENWALD (ed.), *The McGraw-Hill Encyclopedia of Economics,* 2nd ed. (1994). (Ed.)

Utility and value. Two good introductory discussions are ROBERT DORFMAN, *The Price System* (1964), and *Prices and Markets,* 3rd ed. (1978). JOSEPH SCHUMPETER, *History of Economic Analysis,* ed. by ELIZABETH BOODY SCHUMPETER (1954, reissued 1986), is a classic work. An excellent brief discussion can be found in GEORGE J. STIGLER, *Essays in the History of Economics* (1965, reprinted 1987), especially essays 5, 6, and 12. Three rather advanced works on modern value theory are J.R. HICKS, *Value and Capital,* 2nd ed. (1950, reissued 1974); PAUL A. SAMUELSON, *Foundations of Economic Analysis,* enlarged ed. (1983); and J. HÜSLER and R.-D. REISS (eds.), *Extreme Value Theory* (1989), containing conference proceedings. MARC R. TOOL, *Essays in Social Value Theory: A Neo-Institutionalist Contribution* (1986), provides very insightful views.

Seminal works in the history of value theory include DAVID RICARDO, *On the Principles of Political Economy and Taxation* (1817, reissued 1981); F.Y. EDGEWORTH, *Mathematical Psychics* (1881, reprinted 1967); CARL MENGER, *Principles of Economics* (1950, reissued 1981; originally published in German, 1871); LÉON WALRAS, *Elements of Pure Economics; or, The Theory of Social Wealth* (1954, reprinted 1984; originally published in French, 1874); W. STANLEY JEVONS, *The Theory of Political Economy,* 5th ed. (1957); ALFRED MARSHALL, *Principles of Economics,* 9th ed., 2 vol. (1961), also discussing price; JOHN WEEKS, *Capital and Exploitation* (1981), a study of Marx's labour theory of value; HERMANN HEINRICH GOSSEN, *The Laws of Human Relations and the Rules of Human Action Derived Therefrom* (1983; originally published in German, 1854); and K.K. VALTUKH, *Marx's Theory of Commodity and Surplus-Value: Formalised Exposition,* trans. from Russian (1987). Two good discussions of the more recently popular theories of utility are DAVID M. KREPS, *Notes on the Theory of Choice* (1988); and BILL GERRARD (ed.), *The Economics of Rationality* (1993).

Among the best modern textbooks in microeconomics are DAVID D. FRIEDMAN, *Price Theory,* 2nd ed. (1990); DAVID M. KREPS, *A Course in Microeconomic Theory* (1990); and HAL R. VARIAN, *Microeconomic Analysis,* 3rd ed. (1992), and *Intermediate Microeconomics,* 3rd ed. (1993). (W.J.B./Ed.)

Price. Major historical treatises include ADAM SMITH, *An Inquiry into the Nature and Causes of the Wealth of Nations,* 2 vol. (1776, reissued in 1 vol., 1991); and JOHN STUART MILL, *Principles of Political Economy,* 2 vol. (1848, reissued in 1 vol., 1994). Among the best contemporary textbooks are GEORGE J.

STIGLER, *The Theory of Price,* 4th ed. (1987); F.M. SCHERER and DAVID ROSS, *Industrial Market Structure and Economic Performance,* 3rd ed. (1990); PAUL A. SAMUELSON and WILLIAM D. NORDHAUS, *Economics,* 14th ed. (1992); and WILLIAM J. BAUMOL and ALAN S. BLINDER, *Economics,* 6th ed. (1994), and *Macroeconomics,* 6th ed. (1994). FRANK H. KNIGHT, *The Economic Organization* (1933, reissued 1967), presents a classic statement of the functions of an economic system. Selected applied analyses include MILTON FRIEDMAN and ROSE D. FRIEDMAN, *Capitalism and Freedom* (1962, reissued 1982), especially chapters 6–12; JOE S. BAIN, *Essays on Price Theory and Industrial Organization* (1972); REUBEN A. KESSEL, R.H. COARSE, and MERTON H. MILLER (eds.), *Essays in Applied Price Theory* (1980); ARTHUR M. OKUN, *Prices and Quantities: A Macroeconomic Analysis* (1981); and JACK HIRSHLEIFER and AMIHAI GLAZER, *Price Theory and Applications,* 5th ed. (1992).
(G.J.S./Ed.)

Market structure. Noteworthy texts include WILLIAM FELLNER, *Competition Among the Few: Oligopoly and Similar Market Structures* (1949, reissued 1965); JOE S. BAIN, *Barriers to New Competition: Their Character and Consequences in Manufacturing Industries* (1956, reprinted 1993), and *Industrial Organization,* 2nd ed. (1968), a general textbook; CARL KAYSEN and DONALD F. TURNER, *Antitrust Policy: An Economic and Legal Analysis* (1959); EDWARD CHAMBERLIN, *Theory of Monopolistic Competition,* 8th ed. (1962); JOAN ROBINSON, *Economics of Imperfect Competition,* 2nd ed. (1969, reissued 1976); and WILLIAM G. SHEPHERD and CLAIR WILCOX, *Public Policies Toward Business,* 6th ed. (1979), a good general textbook. JOSEPH A. SCHUMPETER, *Capitalism, Socialism, and Democracy,* 6th ed. (1987), provides a still brilliant analysis of various market structures; and MORTON I. KAMIEN and NANCY L. SCHWARTZ, *Market Structure and Innovation* (1982), follows nicely from Schumpeter's book. CHARLES E. LINDBLOM, *Politics and Markets* (1977), is also a classic and an excellent examination of market structures; and RICHARD E. QUANDT and DUSAN TRISKA (eds.), *Optimal Decisions in Markets and Planned Economies* (1990), offers a more current look at themes treated by Lindblom. Special topics related to market structure can be found in DON E. WALDMAN, *Antitrust Action and Market Structure* (1978); and ELHANAN HELPMAN and PAUL R. KRUGMAN, *Trade Policy and Market Structure* (1989). Excellent treatments of industrial organization include JEAN TIROLE, *The Theory of Industrial Organization* (1988), a graduate-level text; RICHARD SCHMALENSEE and ROBERT D. WILLIG (eds.), *Handbook of Industrial Organization,* 2 vol. (1989); and DENNIS W. CARLTON and JEFFREY M. PERLOFF, *Modern Industrial Organization,* 2nd ed. (1994), an accessible intermediate-level text.
(J.S.B./Ed.)

Production. ROLF FÄRE, *Fundamentals of Production Theory* (1988), contains an excellent introductory treatment. Authoritative intermediate-level discussions may be found in WILLIAM J. BAUMOL, *Economic Theory and Operations Analysis,* 4th ed. (1977). VERNON L. SMITH, *Investment and Production* (1961), especially emphasizes the relationship between long-run costs and investment. Probably the best technical presentation is PAUL A. SAMUELSON, *Foundations of Economic Analysis,* enlarged ed. (1983). GEORGE J. STIGLER, *Production and Distribution Theories* (1941, reissued 1994), provides a discussion of the evolution of the theory; while GERHARD ROSEGGER, *The Economics of Production and Innovation: An Industrial Perspective,* 2nd ed. (1986); and FINN R. FØRSUND (ed.), *Topics in Production Theory* (1984), discuss the relationship between theory and empirical data. An interesting survey of recent work in this area is FERNANDO J. CARDIM DE CARVALHO, *Mr. Keynes and the Post Keynesians: Principles of Macroeconomics for a Monetary Production Economy* (1992).
(R.D./Ed.)

Distribution. Analyses of economic distribution appear in DAVID RICARDO, *Principles of Political Economy and Taxation* (1817, reissued 1981), the classical subsistence theory of wages; KARL MARX, *Capital,* vol. 1 (1886; originally published in German, 1867), also available in many later editions, treating the process of distribution as pure conflict; JOHN BATES CLARK, *Distribution of Wealth* (1899, reissued 1965), the classic work on marginal productivity theory; FRANK H. KNIGHT, *Risk, Uncertainty, and Profit* (1921, reprinted 1985); JOSEPH SCHUMPETER, *The Theory of Economic Development* (1934, reprinted 1987; originally published in German, 1912); PAUL H. DOUGLAS, *The Theory of Wages* (1934, reissued 1964), which sets forth the famous Cobb–Douglas function; K.J. ARROW *et al.,* "Capital–Labor Substitution and Economic Efficiency," *The Review of Economics and Statistics,* 43:225–250 (1961); J.R. HICKS, *The Theory of Wages,* 2nd ed. (1963, reissued 1973), a sophisticated treatment of marginal productivity theory; and NICHOLAS KALDOR, "Alternative Theories of Distribution," in his *Essays on Value and Distribution,* 2nd ed. (1980), a discussion of various theories from Ricardo to Keynes. DAN USHER, *The Economic Prerequisite to Democracy* (1981), suggests that democracy requires broad agreement on how an economic system will distribute wealth. Other works in this area are ALAN S. BLINDER, *Toward an Economic Theory of Income Distribution* (1974); and RONALD G. EHRENBERG and ROBERT S. SMITH, *Modern Labor Economics: Theory and Public Policy,* 5th ed. (1994).
(K.E.Bo./P.L.Kl./H.O.Sc./J.P./Ed.)

Consumption. The two classic references for understanding the modern theory of consumption are FRANCO MODIGLIANI and RICHARD BRUMBERG, "Utility Analysis and the Consumption Function: An Interpretation of Cross-Section Data," in KENNETH K. KURIHARA (ed.), *Post-Keynesian Economics* (1954, reissued 1993), pp. 388–436; and MILTON FRIEDMAN, *A Theory of the Consumption Function* (1957). JOHN KENNETH GALBRAITH, *The Affluent Society,* 4th ed. (1984), studies the social and economic consequences of advanced industrialism. THORSTEIN VEBLEN, *The Theory of the Leisure Class* (1899, reissued 1994), argues that the consumption of the wealthy classes is aimed mainly at demonstrating status rather than satisfying basic needs. E.J. MISHAN, *The Costs of Economic Growth,* rev. ed. (1993), critiques the goal of economic growth as a major aim of policy. VANCE PACKARD, *The Hidden Persuaders,* rev. ed. (1980), provides a somewhat partisan attempt to show that advertising techniques create artificial wants through psychological manipulation. A textbook covering modern consumption theory at an advanced level is ANGUS DEATON and JOHN MUELLBAUER, *Economics and Consumer Behavior* (1980); and an excellent survey on recent contributions to this area is ANGUS DEATON, *Understanding Consumption* (1992).
(J.A.C.B./Ed.)

Economic fluctuations. Good introductions to the study of business cycles include ERIK LUNDBERG (ed.), *The Business Cycle in the Post-War World* (1955, reprinted 1986); and ALVIN HARVEY HANSEN, *Business Cycles and National Income,* expanded ed. (1964). Famous surveys of business cycle theories are JOSEPH A. SCHUMPETER, *Business Cycles,* 2 vol. (1939, reprinted 1982); and GOTTFRIED HABERLER, *Prosperity and Depression,* 5th ed. (1964). J. TINBERGEN, *Statistical Testing of Business-Cycle Theories,* 2 vol. (1939, reissued 2 vol. in 1, 1968), attempts to verify by econometric analysis the theories surveyed in Haberler's work. The nontheoretical approach to business-cycle research is set forth in ARTHUR F. BURNS and WESLEY C. MITCHELL, *Measuring Business Cycles* (1946); and further developed in GEOFFREY HOYT MOORE, *Business Cycle Indicators,* 2 vol. (1961). History and politics are dealt with in VIVIAN WALSH and HARVEY GRAM, *Classical and Neoclassical Theories of General Equilibrium* (1980); DENNIS C. MUELLER, *Public Choice II* (1989); and JAMES E. ALT and KENNETH A. SHEPSLE (eds.), *Perspectives on Positive Political Economy* (1990).

Two good introductions to macroeconomics are GEORGE T. MCCANDLESS, JR., *Macroeconomic Theory* (1991), neoclassical in approach; and JOSEPH STIGLITZ, *Economics* (1993), Keynesian-oriented. At the intermediate level, the two competing alternatives for reaching a sound understanding of national income theory are ROBERT J. BARRO and VITTORIO GRILLI, *European Macroeconomics* (1994), which applies the intertemporal equilibrium approach to macroeconomic analysis; and RUDIGER DORNBUSCH and STANLEY FISCHER, *Macroeconomics,* 6th ed. (1994), which follows an IS-LM approach. Three advanced textbooks in macroeconomic theory are THOMAS J. SARGENT, *Macroeconomic Theory,* 2nd ed. (1987), and *Dynamic Macroeconomic Theory* (1987); and OLIVIER JEAN BLANCHARD and STANLEY FISCHER, *Lectures on Macroeconomics* (1989).

More specialized or intensive treatments of macroeconomics are JOHN MAYNARD KEYNES, *The General Theory of Employment, Interest, and Money* (1936, reissued 1991), the classic theoretical work in the field; SEYMOUR E. HARRIS (ed.), *The New Economics: Keynes' Influence on Theory and Public Policy* (1947, reprinted 1973); and GARDNER ACKLEY, *Macroeconomic Analysis and Theory* (1978), an introductory text. Later evaluations by leading economists of the significance and influence of Keynesian ideas may be found in ROY F. HARROD, *The Life of John Maynard Keynes* (1951, reissued 1982), offering insight into the genesis of Keynes's ideas; ROBERT LEKACHMAN (ed.), *Keynes' General Theory: Reports of Three Decades* (1964); AXEL LEIJONHUFVUD, *On Keynesian Economics and the Economics of Keynes* (1968); and HERBERT STEIN, *The Fiscal Revolution in America,* rev. ed. (1990).

Some important perspectives on the successes and failures of economic strategies that have resulted in fluctuations are JOHN KENNETH GALBRAITH, *Economics and the Public Purpose* (1973), and *Economics in Perspective: A Critical History* (1987); and DOUGLASS C. NORTH, *Institutions, Institutional Change, and Economic Performance* (1990). Two other works that offer perspectives on economic theory and its applications are NEIL DE MARCHI and MARK BLAUG (eds.), *Appraising Economic Theories* (1991); and MARK BLAUG, *The Methodology of Economics; or, How Economists Explain,* 2nd ed. (1992).
(H.Gu./Ed.)

Ecuador

Ecuador (in full, Republic of Ecuador; Spanish: República del Ecuador), a country of northwestern South America, straddles part of the Andes Mountains and occupies part of the Amazon basin. Lying on the Equator, from which its name derives, it borders Colombia to the north, Peru to the east and the south, and the Pacific Ocean to the west; it includes the Pacific island group of the Galápagos Islands, or the Archipiélago de Colón. It has an area of 103,930 square miles (269,178 square kilometres)—more than twice the size of Nicaragua—including 100,844 square miles on the South American continent. A series of border disputes with Peru, which erupted periodically into warfare during the 20th century, were resolved by treaty in 1998. The capital, Quito, is located in the Andean highlands in the north-central part of the country.

Ecuador is one of the most environmentally diverse countries in the world, and it has contributed notably to the environmental sciences. The first scientific expedition to measure the circumference of the Earth, led by Charles-Marie de La Condamine, was based in Ecuador; research in Ecuador by renowned naturalists Alexander von Humboldt and Charles Darwin helped establish basic theories of modern geography, ecology, and evolutionary biology. Ecuador has a deeply ingrained cultural heritage. Much of what is now Ecuador came to be included in the Inca empire, the largest political unit of pre-Columbian America. Economically, Ecuador has become known for exporting (erroneously named) Panama hats and agricultural products, notably bananas. Its history has been marked by political and economic challenges, including long periods of military rule, boom-and-bust economic cycles, and inequitable distributions of wealth. Ecuador is unusual among Latin American nations in having two major centres of population and commerce—with the vibrant port city of Quayaquil acting as a counterbalance to Quito.

This article focuses on the land and people of continental Ecuador; for information on the Galápagos Islands, see the *Micropædia:* GALAPAGOS ISLANDS.

This article is divided into the following sections:

Physical and human geography

THE LAND

Relief. The Ecuadoran mainland is divided into three main physical regions: the Costa (coastal region), the Sierra (highland region), and the Oriente (eastern region, also called the Amazon region). The Costa is composed of lowlands that extend eastward from the Pacific Ocean to the western edge of the Andes and rise from sea level to an elevation of 1,650 feet (500 metres). Running north-south, small coastal mountain ranges—the Colonche, Chindul, and Mache mountains—rise to 2,600 feet. Between these coastal ranges and the Andes, interior valleys are mantled with silt deposits left by rivers that largely drain into the Gulf of Guayaquil. Puná, in the gulf, is the major island.

The Costa

The western and central ranges of the Andes bordering the Sierra constitute the country's highest and most continuous mountain chains. Many peaks are volcanic or snow-covered; these include Cayambe, 18,996 feet (5,790 metres); Antisana, 18,714 feet (5,704 metres); Cotopaxi—the world's highest active volcano—19,347 feet (5,897 metres); Chimborazo, 20,702 feet (6,310 metres); Altar, 17,451 feet (5,319 metres); and Sangay, 17,158 feet (5,230 metres). The two ranges are connected at intervals by transversal mountain chains, between which are large, isolated valleys or basins, called *hoyas.*

The Oriente begins with the eastern spur of the central range, which extends to the border with Peru. This region is crossed by the eastern—and least important—cordillera of the Andes, also composed of three sections: the Cordillera de Galeras, which includes the northern mountains and such peaks as Reventador (11,434 feet) and Sumaco (12,759 feet); the Cordillera de Cutucú, which borders the Upano valley and includes the central peaks; and the Cordillera del Cóndor to the south, which borders the Zamora valley. Beyond this eastern cordillera, to the east, is the Amazon basin, extending below 900 feet.

The volcanic Galápagos Islands consist of 19 rugged islands and scores of islets and rocks situated about 600 miles west of the mainland. The largest island, Isabela (Albemarle), rises to 5,541 feet (1,689 metres) at Mount Azul, the archipelago's highest point. The second largest island is Santa Cruz.

Drainage. Numerous rivers originate in the mountains, pass through the hoyas of the Sierra, and flow either west to the Pacific coast or east to the Amazon River. The main watercourse of the Costa is the Guayas River. Formed by the juncture of the Daule and Babahoyo rivers and their affluents, the Guayas River is navigable for the greater part of its course. Other rivers that flow to the ocean include the Santiago, the Cayapas, the Esmeraldas, and the Naranjal.

In the Sierra the rivers, which are torrential in their upper courses, become calmer in the plains areas but remain, nonetheless, unnavigable.

The rivers of the Oriente carry the greatest volume of water. The most important is the Napo River, which receives the Coca and Aguarico rivers as well as other large tributaries as it takes its course toward Peru, where it joins the Amazon River. Other large rivers include the Pastaza, Morona, and Santiago, all of which drain into the Marañón River in Peru.

Soils. Ecuador's soils are among the most varied on

MAP INDEX

Political subdivisions

Cities and towns

Earth. Volcanic activity at higher elevations in the Andes has resulted in the formation of fertile volcanic and prairie soils, such as andosols and mollisols, with dark surface layers rich in organic matter. The soils are typically, however, underlain by a yellow-coloured hardpan, locally called *cangahua*, which is often exposed on eroded steeper slopes. The eroded topsoil accumulates on lower slopes and especially on flats, which form the most desirable locations for agriculture. Indigenous peoples have developed effective methods for the fertilization of these soils, including the use of native manures, the mounding of fertilizing muck from drainage ditches, the creation of raised fields, and the use of irrigation canals.

Traditional fertilization methods

In the Costa the floodplains of the Guayas and other rivers have accumulated fertile silts from the highlands. These coastal soils are of great fertility but often consist of clays that are subject to shrinking and swelling and thus present problems for construction. The effectiveness of traditional methods of managing these soils has come to be recognized, and such techniques as embanked fields for runoff management (*albarradas*) and raised fields (artificially constructed earthen platforms built on shallow lakes or marshy areas) are encouraged.

In the Amazon basin, soils have not been fully studied and mapped; nevertheless, it appears that soils there are quite diverse, including areas of fertile alluvial soil, organic soils called histosols, and more weathered tropical soils called oxisols. The latter may be used for crops with appropriate technology, such as shifting cultivation or agroforestry (crops and useful trees managed together), but some agronomists suggest that they are better utilized for timber and other renewable tropical forest products.

Climate. Because Ecuador lies on the Equator, most of the country, except in the Sierra, experiences humid tropical climates. The Oriente is influenced throughout the year by an unstable maritime tropical air mass, while the Costa is subject to greater variations associated with seasonal movements of the intertropical convergence zone and the cold Peru Current. Local convectional processes dominate the weather in the higher parts of the Andes.

The Oriente experiences fairly continuous and abundant rainfall and high temperatures. The Costa generally has a wet season in the first half of the year and a relatively dry one in the second half. In some years, warm water collects off the coast, causing the weather phenomenon known as El Niño; this can result in torrential downpours that cause devastating ecological damage on the coast and occasionally even in the highlands. In the Sierra, rains reach a maximum during the equinoxes; there is a long dry season from June to September and a shorter one from December through January.

Ecuador has a small area of truly dry climate at the Santa Elena Peninsula along the southern coast, with annual rainfall decreasing from 40 inches (1,000 millimetres) near Guayaquil to only 4 inches at Salinas. In the highlands, annual rainfall decreases toward the centres of the canyons and valleys, sometimes dropping below 20 inches or even below 10 inches. Most of the country, however, is humid, receiving more than 20 inches of rain a year. The southern coast and the highlands receive 30 to 80 inches. The wettest areas, the northern coast and the Oriente, receive 120 to 240 inches of rain.

Both the Costa and the Oriente regions are warm, temperatures varying only slightly among the seasons; much wider differences occur between day and night. Average daytime high temperatures range from 84° to 91° F (29° to 33° C), while nighttime lows fall to between 68° and 75° F (20° to 24° C). As elevation increases, temperatures drop fairly predictably at a rate of about 9° to 11° F (5° to 6° C) for every 3,300 feet. Pleasantly temperate climates occur between elevations of 2,600 and 6,600 feet. At higher elevations, frost is a possibility, especially in areas of flat relief and during cloud-free nights of the dry seasons. Above elevations of 11,800 to 12,500 feet agriculture becomes increasingly difficult because of the shrinking growing season and increasing frost hazard, and above about 16,400 feet the peaks are snowcapped.

Temperature variations

Plant and animal life. The wet lowlands of the Oriente and the northern and southeastern corners of the Costa are covered with tropical rain forest, containing various trees, lianas, and many epiphytes. This forest thickens as it approaches the zone of maximum rainfall, which occurs between 4,000 and 5,000 feet above sea level. In the Guayas River valley, the forest includes balsa, which is exploited for its light lumber; in the eastern forest the cinchona trees were a valuable source of quinine before synthetic equivalents reduced demand for it. The trees of the Costa are fast disappearing because of exploitation, while the Oriente is increasingly under attack by commercial interests seeking to establish ranches or plantations.

In the Costa between Esmeraldas and the Gulf of Guayaquil, where the climate is affected by the Peru Current, the northern rain forest gives way southward to deciduous and semideciduous woodland. There, scattered palms produce the ivory-coloured tagua nuts used in making buttons, while the hat carludovica (*Carludovica palmata*) furnishes the fibre used for Panama hats. Areas of swampy coast and the river floodplains were once covered by thick mangrove forest, but much of it has been removed to make way for shrimp aquaculture.

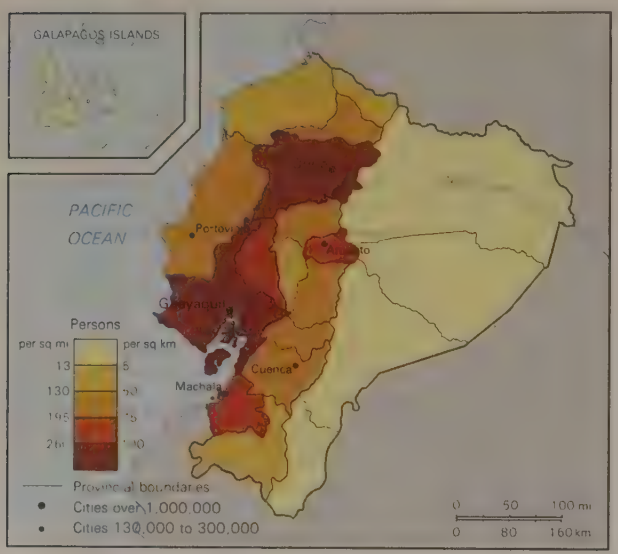
In the Sierra the decreasing growths of native vegetation of the dry valley interiors consist of a thorny woodland, which gives way toward the valley edges to a low evergreen forest and, at higher elevations, to the bunchgrasses of the high paramo. Much of the highland vegetation has been removed for agriculture or altered by periodic burning.

Rain forest fauna

In the rain forest live a wide variety of monkeys, as well as such carnivorous mammals as jaguars, ocelots, foxes, weasels, otters, skunks, raccoons, coatis (raccoon relatives), and kinkajous (tree-dwelling nocturnal animals). Hoofed mammals include the tapir, deer, and peccary. Numerous species of rodents and bats inhabit the area.

Ecuadoran bird and fish life is notably rich. Some 1,500 species of birds have been identified, different species of birds being associated with the various types of vegetation. Among many types of North American birds that migrate to Ecuador for the winter are the Virginia rail, the kingbird, the barn swallow, and the scarlet tanager. The fish population is similar to that of the Amazon River, although in the west the electric eel and the piranha are not found. All major groups of reptiles are represented.

Settlement patterns. In colonial and early modern times most people lived in the rural Sierra. By the late 20th century the growth pattern had changed, and the population majority shifted to the lowland regions, especially the Costa.



Population density of Ecuador.

In the highlands, traditional Indian and mestizo villages, hamlets, and scattered farmsteads are associated with a checkerboard pattern of small agricultural plots of corn (maize), potatoes, barley, wheat, broad beans, kidney beans, and domesticated lupine, alternating with fields temporarily lying fallow and used for grazing. Sheep are grazed on fallow land and higher-elevation pastures. Traditional housing of wattle and daub, thatch, or rammed earthen walls, with thatched roofs, has been giving way to Spanish tile or corrugated metal roofs and cement block or brick walls. Prior to the 1960s, small-scale farmers lived in a dependent relationship with large-scale haciendas, which controlled the best flat land and high pastures. Since the 1960s, land reform and economic changes have resulted in the subdivision of haciendas into more profitable medium-sized commercial farms producing dairy products, new potato varieties, fruits, and vegetables. In some cases the old rural hacienda buildings, with white walls and Spanish tile roofs, are still occupied by farm owners; in others the buildings have been abandoned by owners moving to the city or have been converted into hotels. Highland villages and towns were usually built on the Spanish colonial grid plan, which was centred on one or more plazas distinguished by church and governmental buildings.

Coastal region farming

On the coast, farmers working small plots practice a mixed tropical agriculture, growing such crops as cassava (manioc), peanuts (groundnuts), bananas, plantains, coffee, cacao, and corn; they live in houses on stilts, walled with flattened bamboo and roofed with thatch. Larger farms produce quantities of rice, cocoa, bananas, and African oil palm, while ranches raise beef cattle. Parts of the coast were colonized by mid-20th-century mestizo pioneers, especially the area to the west and northwest of Quito around Santo Domingo de los Colorados; isolated Indian populations have gradually been reduced to minority status. A similar process has been occurring in the Oriente, with oil fields and new highways allowing highland mestizos and South American Indians to move into areas settled by Amazonian Indian groups.

By the 1982 census half of the Ecuadoran population had become urban dwellers, with half of the urban population living in the two major cities. Guayaquil is the largest city, the major port and commercial centre, and also the cultural centre of the Costa. Quito, apart from its governmental activities, has become an important regional headquarters for international organizations working in the Andes and has attracted a substantial tourist trade. Other cities are much smaller, but Esmeraldas, Manta, Portoviejo, and Machala are important coastal agricultural and trade centres, and Ambato and Cuenca are the largest and most dynamic highland trade centres outside of Quito.

THE PEOPLE

Ethnic and linguistic composition. The ethnic groups of Ecuador include a number of Indian-language-speaking populations, blacks, mestizos, whites, and immigrants from a variety of foreign countries, including Lebanon, China, Korea, Japan, Italy, and Germany. Most modern censuses have not inquired about ethnicity, language, religion, or origin, so that the numbers of different groups are not precisely known. The main population components are highland and lowland mestizos.

There may have been about 700,000 Indian-language speakers as of the mid-1980s, primarily Quechua (Quichua) speakers in the Sierra. The highland Quechua speakers, many of whom are bilingual in Spanish, have only recently come to identify themselves ethnically with regions beyond their local villages; they often refer to themselves as Runa (people). They are concentrated in several distinct districts: to the north of Quito, in the vicinity of Otavalo and Cayambe; in the central highlands, from the vicinity of Latacunga to beyond the southern border of Chimborazo *provincia* and including the distinctive Salasacas Indians who live south of Ambato; in scattered areas around Cuenca in the south-central highlands; and to the north of Loja, where the Saraguro Indians live. In the southeastern lowlands is the large group of the Shuar and Achuar Indians, related to similar groups across the border in Peru; the lowland Quechua speakers (made up of several groups) occupy much of the central Amazon lowlands, along with the Huaorani (Auca), who live in a protected reserve. In the northern Oriente are the small groups of Cofán and Siona-Secoya. The Costa, from north to south, includes small Indian groups: the Awá (Kwaiker), Cayapa (Chachi), and Colorados (Tsáchila).

Black ethnic groups

The blacks of Ecuador are the descendants of slaves imported from Africa; they consist mainly of the coastal blacks of Esmeraldas *provincia* to the northeast and the highland blacks of the Chota River valley in the northern highlands. Both groups have distinctive cultures and are well-defined as ethnic groups.

Highland mestizos include numerous rural folk who occupy areas of the highlands adjacent to the Indian highland groups, as well as town and city dwellers. Mestizos of the central highlands are perhaps closest to being typical highland Ecuadorans, with little tendency to identify themselves as a distinct ethnic group or regional culture, except in the case of those living in the larger cities. Mestizos from the far southern highlands, called Lojanos, are more distinctive in lifeways and have been especially active in colonizing the Oriente and the Costa. Lowland mestizos of the Costa sharply differ from highlanders in diet, dialect, music, and identity.

Spanish is the language of business and government, although there are dialectal differences between Sierra and Costa Spanish, and Sierra Spanish has been influenced by Quechua. Most Indian males are bilingual. Several Indian languages will likely persist as mother tongues, and the concepts of bilingualism and bilingual or bicultural education are becoming increasingly important.

Religion. Ecuador is overwhelmingly Roman Catholic. The Roman Catholic church plays a significant role in

education and social services and influences the selection of significant places for festivals and pilgrimage sites, such as Quinche in the north and Biblián in the south. Protestantism continues to grow rapidly, particularly among the disadvantaged, with the largest groups being non-Pentecostal Evangelicals and Pentecostals. There is also a sizable Mormon congregation. Quito, Ambato, and Guayaquil have been urban centres of Protestant activity, and many of the Indians of the Sierra and Oriente have also converted. In Sierra *provincias* such as Carchi, Azuay, and Loja and in Manabí *provincia* in the Costa, there has been more reluctance to accept Protestant conversion. A small Jewish population is concentrated in Quito, and there are also some Bahāʾī adherents.

Demographic trends. Ecuador, like other Andean countries, has experienced a population boom, the result of a decreasing death rate and a continued high birth rate. This rapid growth has resulted in a relatively young population. The country has attracted immigrants from neighbouring Colombia and from East Asia, and there has also been a small migration from Chile, including political refugees. Significant numbers of Ecuadorans have emigrated to the United States. Deprived northern highlanders tend to migrate to Quito, seeking opportunities for income not available in the countryside. The rural coastal people, on the other hand, have generally migrated to the north-central Costa and to Guayaquil, and the southern highlanders to the southeastern and northeastern Oriente and to the north-central Costa, as well as to Quito and Guayaquil. In areas where people can generate a more substantial cash income, migration has been slower.

THE ECONOMY

Ecuador is a country of enormous economic potential. Development has focused on agricultural, marine, and mineral resources, with industry playing a more limited role. The subsequent production of primary goods has been subject to cycles of boom and bust, however, and Ecuador has sought to diversify its resource exports and to seek new markets. The country has made improved standards of living, but it is still characterized by marked inequalities of wealth and well-being.

Boom and bust cycles

Resources. Ecuador's major resource is its soil, which, with its generally adequate rainfall and diverse climates, allows a wide variety of agricultural production. Particularly rich soils are found in the Guayas and other river floodplains on the coast and in the flats, floodplains, and volcanic slopes of the highlands.

The full mineral potential of Ecuador is still being discovered. There are gold deposits throughout the country and oil deposits in the northeastern Oriente. Explorations have discovered significant deposits of natural gas in the Gulf of Guayaquil, large deposits of low-grade copper ore west of Cuenca, and deposits of silver, molybdenum, iron ore, gypsum, zinc, and lead at various locations.

Forest and marine resources are also exploited. Traditional coastal dwelling construction is based on the native bamboo, and in the highlands pine and eucalyptus plantations provide fuel and construction material. A small-scale fishing industry operates mainly out of ports on the western coasts of Guayas and Manabí *provincias*. The major marine product, however, is shrimp, produced in large ponds constructed in coastal mangrove swamps. A growing problem has been the excessive destruction of these mangroves and the subsequent threat to shrimp production caused by an inadequate supply of shrimp larvae and juvenile shrimp, which are either captured in the swamps or bred by hatcheries.

The Andes Mountains present vast possibilities for hydroelectric development. The construction of larger hydroelectric plants, particularly the Agoyan and Paute projects, has notably improved hydroelectric potential, albeit with serious problems of siltation. A government agency is responsible for the development of power resources.

Agriculture. Agriculture has traditionally employed a large proportion of the population. Many Ecuadorans feed their families with the produce from their own farms; production of these subsistence crops, including corn, potatoes, beans, and cassava, is important but not accurately reflected in official figures. Commercial production of grain crops has been discouraged by imports of inexpensive grains from the United States; these imports have also encouraged a shift in diet away from traditional corn consumption and toward rice and wheat. Production of tropical specialty crops such as bananas, cacao, rice, and coffee have provided much-needed foreign exchange. Dependence on foreign imports of edible oil-producing crops and vegetable oils has been reduced through cultivation of the African oil palm. Livestock raising is widespread, with beef cattle being produced in the lowlands and dairy cattle and sheep in the highlands; chickens consume feedstuffs produced from locally grown hard corn and other crops. Pigs are raised on a small scale, but their meat does contribute to the diet, especially in the highlands. Goats are important as a source of meat in Loja *provincia* in the south, while guinea pigs are raised for food in the highlands.

Livestock raising

Mathias Oppersdorff—Photo Researchers

Farmers digging potatoes near Hacienda Zuleta in the Sierra region northeast of Quito.

Only a small proportion of the Ecuadoran territory has been reclaimed for cultivation, although unreclaimed land is valuable as forest reserves and wildlife habitats. Chemical fertilizers are mainly employed on commercial crops, while traditional farmers employ animal manures; still, overall yields could be vastly increased. Irrigation has been employed since prehistoric times in the highlands, and up to half the highland production by value is from irrigated fields; there is little further potential for expanding the highland irrigated area, however. In contrast, irrigation has been expanding rapidly on the coast.

Mining and industry. Oil and gold are the most valuable mined products. Gold has been produced in Ecuador for centuries, and much of the production comes from remote gold districts such as Nambija in Zamora *provincia*, where thousands of families live with minimal services and the miners face hazardous conditions in tunnels subject to collapse due to torrential rains. Oil extracted in the northeast and sent over the Andes via pipeline has become Ecuador's major mineral export. The state oil company operates in consortia with foreign corporations.

Industrial development is still in the early stages. Some industry is associated with the processing of primary products, including cement, refined sugar, chocolate bars, beer, pasta, bread, and instant coffee. Some import-substitute industries licensed by foreign corporations have been established, including those producing pharmaceuticals and tires and those assembling automobiles. Ecuador has had some success exporting processed foods, such as

fruit drinks and canned meats, to neighbouring countries. Ecuadoran woolen tapestries and sweaters; crafts in wood, straw, ceramics, leather, and tagua nut (called vegetable ivory); and Panama hats contribute to the economy. On a larger scale the textile and agricultural processing industries both seem promising for long-term growth.

Finance and trade. The Central Bank of Ecuador and the National Bank of Promotion, both state-controlled, have branches in all the provincial capitals. The former is the government depository and controls the monetary system, while the latter handles agricultural and industrial credit. Private or commercial banks are both foreign and domestic. The bank supervisory board is a technical organization that monitors all banking activities.

Exports include crude oil and derivatives, shrimp, bananas, coffee, and cocoa; these are sold primarily to the United States, Germany, Singapore, Panama, and Peru. Imports include machines and primary industrial materials, motor vehicles, consumer goods, and food and chemical products, bought mainly from the United States, Japan, Venezuela, Germany, Brazil, and Mexico.

Transportation. For much of its history, Ecuador relied on horse or mule transport on difficult trails or on canoe transport on coastal or Amazon river systems. Railroad development faced great difficulties, and the Quito-to-Guayaquil rail line (with a branch to Cuenca)—although locally important—is slow, antiquated, and subject to disruption by floods, landslides, and earthquakes. This is even more the case for the rail line from Quito to San Lorenzo on the coast via Ibarra. Transport was revolutionized by the paving of the Pan-American Highway, the main Ecuadoran roadway, which extends the length of the highlands from the Colombian to the Peruvian border. It is supplemented by a growing network of all-weather roads. The main highland centres are connected by asphalt roads, with asphalt or cobblestone secondary roads to regional market towns. Many rural centres are still served only by unsurfaced roads, impassable during wet periods; roads to the east of the Andes are also relatively poor. There is some concern that highway development will lead to deforestation and have adverse effects on the survival of remote Indian groups. The more likely reason for slow development, however, has been cost.

Railroad development

Goods are brought to market through labour-intensive methods by independent truckers and by peasant women and itinerant vendors, who bring small amounts of goods to market on foot, with burros or mules, or by bus. Numerous regional bus companies provide cheap, frequent, and far-ranging rural transport.

Air transport has grown, especially for the important Quito-Guayaquil connection and for international travel. The major state-controlled international airline is Compañía Ecuatoriana de Aviación, but several other international carriers serve Ecuador, landing at the major airports of Guayaquil and Quito. Other domestic airlines serve local airports, and air service to centres such as Cuenca and Machala has been established. Other air services provide access to points in the Oriente.

Guayaquil is the country's chief port, with modern facilities at Puerto Nuevo. Other modern ports include San Lorenzo, Esmeraldas, Manta, and Puerto Bolívar. Rivers, particularly in the Guayas basin, also serve as transportation arteries.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Ecuador is a sovereign democratic republic. The president and vice president are elected for four-year terms by popular, direct, and secret voting; the president may not be reelected to a second term. The chief executive is aided by a cabinet. Legislative power is vested in the unicameral National Chamber of Representatives (also called National Congress). Twelve of its members are popularly elected to four-year terms at the national level; the remaining 59 are elected to two-year terms at the provincial level.

Local government

The chief executive appoints as his representatives the provincial governors, the political chiefs in each of Ecuador's 20 *provincias,* which are divided into *cantones* (regions); these in turn are divided into *parroquias* (parishes). The chief executive also appoints the political chief in each *cantón* and a political lieutenant in each parochial district. Every province also has a provincial council presided over by the provincial prefect.

Each *cantón* constitutes a municipality, the governing of which is in the hands of a *cantón* council. The council of each provincial capital is headed by a mayor.

An array of Ecuadoran political parties draws strength from various regions, classes, ethnic groups, and professions. No party is strong throughout the country, so that alliances must be established to attain victory at the national level. Among the prominent parties is the Democratic Left party, with strength among teachers, government workers, and professionals in the more prosperous parts of the Sierra. The communist parties include the Democratic Popular Movement and the Left Broad Front, with strength in Quito and Loja, while the Ecuadoran Socialist Party has shown strength in the poorer northern and central highlands. The Popular Democracy party is a moderate party with strength in the Quito area. Centrist coastal political parties are often populist in character, associated with charismatic personalities and grass-roots political organizations. Centrist parties with strength on the coast include the Alfarista Radical Front, the Concentration of Popular Forces, and the Ecuadoran Roldosist Party. The Social Christian Party is more conservative.

Prominent political parties

Supreme Court justices are elected for terms of four years. The 16 justices are elected in theory by the National Congress, but in 1984 they were chosen by the government. There are 10 higher courts.

Education. The network of public education has been greatly expanded to promote the goal of universal literacy. Primary education is free and compulsory for six years beginning at age six. Ecuador has made progress in making education available to disadvantaged classes and ethnic groups and to women. Religious and nondenominational private schools also play a significant role. Population growth and limited funding have placed great strains on the educational system, however. Efforts are under way as well to adapt the curriculum to Ecuador's cultural diversity.

Secondary education varies from seriously overcrowded public institutions to elite private institutions emphasizing bilingualism in English, French, or German. The premier university is the Pontifical Catholic University in Quito, noted for its research programs in fields such as botany, archaeology, linguistics, and anthropology. The Polytechnic School in Quito has good programs in the sciences. There are numerous other universities with special strengths in particular areas, although the university system in general has suffered from uncertain funding and political turmoil. Many Ecuadorans seek training abroad, especially in technical fields and in business.

Universities

Much research takes place outside the universities. Geographic and environmental research and postgraduate training are conducted by the Panamerican Centre for Geographic Studies and Investigation at the Military Geographical Institute in Quito. That same building houses other environmental institutes, libraries, and laboratories. Social science institutes are also numerous, especially in Quito; they include the Andean Centre of Popular Action and a local unit of the Latin American Faculty of Social Sciences. Agricultural research is concentrated in the laboratories of the National Institute of Agricultural Investigations. Major research establishments are maintained by French and U.S. foreign assistance organizations.

Health and welfare. All public and private employees are affiliated with the National Social Security Institute. In return for a monthly deduction from employees' salaries, the agency provides such services as medical and hospital insurance coverage, state-run clinics and dispensaries, low-interest loans for surgery and mortgages, retirement pensions for civil and state employees, and pensions for widows and child dependents.

The Social Welfare Program, a division of the Ministry of Public Health, maintains public hospitals in all the provincial capitals and in the principal *cantones.* Little of the national budget is, however, devoted to public health programs, and health conditions are generally poor. A

number of endemic diseases persist, including goitre, typhoid fever, and tuberculosis.

CULTURAL LIFE

Ecuador, as discussed above, is a country of great ethnic diversity and great contrasts of wealth and poverty. People identify more with their region or village than with the country as a whole, although the government has attempted to nourish a sense of pan-Ecuadoran national identity. At a minimum the country may be divided into a dozen or so major folk-cultural regions: *norteño* mestizo, northern Quechua, central highland mestizo, Quiteño urban, central Quechua, Cuencano mestizo, Lojano mestizo, southern Quechua, Esmeraldeño black, coastal mestizo-mulatto, Shuar (Jivaro), and Amazonian Quechua. Numerous smaller or more localized cultures also exist, and there are two culturally mixed areas in the Santo Domingo and northeastern Oriente frontiers. The most prominent and representative groups are the central highland mestizos and coastal mestizo-mulatto mixed culture.

Daily life. Most Ecuadorans place great emphasis on the family, and they also create fictive kinship, which is established by the choice of godparents at baptism. Apart from baptism, important occasions in the life cycle include the 15th birthday of girls, marriage, and funerals. Many Ecuadorans make pilgrimages or dedicate themselves to the service of a particular saint. During the year, numerous religious festivals provide opportunities for parades, special food, and music and dance. Often particular holidays are associated with particular cities, such as the Day of the Dead in Ambato or Carnival in Guaranda, and they attract people from various parts of the country. The Festival of San Juan Bautista is especially important for the Indian populations of the northern highlands, who regard the holidays as an occasion for dance and music.

Festivals and holidays

Easter is an opportunity to eat *fanesca,* a soup that is close to being the Ecuadoran national dish. The soup—made of onions, peanuts, fish, rice, squash, broad beans, *chochos* (lupine), corn, lentils, beans, peas, and *melloco* (a highland tuber)—combines highland and lowland ingredients and is a culinary model of the union of diverse national characteristics. Chili sauce (*ají*) is part of most meals. Empanadas are deep-fried and stuffed savoury pastries. Typical of the coast is ceviche, made with shrimp or shellfish or even mushrooms pickled with lemon juice, cilantro (coriander), and onions. Coastal cuisine also includes deep-fried plantains and various rice dishes. Highland cuisine is based on soups and stews, including quinoa soup and barley soup, and on complex soups and stews mixing various combinations of corn, potatoes, oca, quinoa, *melloco,* beans, barley, broad beans, and squash.

Highland Indian males may wear coloured ponchos—for instance, blue in the Otavalo area and red in western Chimborazo. Traditional footwear is the sandal, and a variety of traditional hats may be worn; in some locations hair is still worn long, gathered in a ponytail. Highland Indian women may wear embroidered blouses, wrapped skirts of woolen cloth, shawls attached with a pin in front, sandals, and locally common hats or headgear.

The arts. Ecuador has a rich tradition of folk art. Quito was a colonial centre of wood carving and painting, and artisans still produce replicas of the masterpieces of the Quito school. Certain mestizo and Indian communities have specialized in particular crafts, such as agave-fibre bags near Riobamba and Salcedo; wood carving at San Antonio de Ibarra; leatherwork at Cotacachi; woolen tapestries at Otavalo, Doctor Miguel Egas, and Salasaca; carpets at Guano; and Panama hats at Montecristi and near Cuenca. Folk music is equally rich, including the well-known *yumbo* and *el sanjuanito* from the highlands and the pasillo from the lowlands, as well as the varying local black and Indian (Amazonian, highland, and coastal) traditions. A revival of interest in folklore among the urban populations has led to the creation of folkloric dance troupes. Modern music is influenced by the Colombian *cumbia* and the Caribbean *salsa* and recorded by Ecuadoran groups with local themes.

Folk architecture is also rich, with varying traditions in bamboo, adobe, rammed earth, wattle and daub, and wood; modern architects have come to realize the continued potential of these traditions. The architectural monuments of the country include the large tolas (pre-Inca ramp mounds) of the northern highlands, such as those protected at the Cochasquí archaeological park; the Inca stone walls of Ingapirca near Cañar; the great colonial churches of Quito—especially San Francisco and la Compañía—with their paintings, statuary, and gilt wood carving; and the entire old urban centre of Quito, the site of a preservation and renovation project.

Modern fine arts are active, the best-known international figure probably being the painter Oswaldo Guayasamín, who is of mestizo-Indian parentage. A somewhat controversial figure, he earned an international reputation depicting the social ills of his society. Jorge Icaza's indigenist novel *Huasipungo,* which depicts the plight of Andean Indians in a feudal society, has also received international attention. Many novelists have come from the coast, including a "Guayaquil group" that explored life among the montuvio (mixed Indian, black, and white) population in a spirit of social realism; coastal novelists of note have included Luis Martínez, Demetrio Aguilera Malta, Joaquin Gallegos Lara, Enrique Gil Gilbert, Alfredo Pareja Diez-Canseco, and José de la Cuadra. Cuenca has been known for its poets, including Jorge Carrera Andrade and César Dávila Andrade. Books are published by both private and public presses, and the people have access to large book fairs and well-stocked bookstores.

Art and literature

Cultural institutions. The Central Bank of Ecuador, headquartered in Quito, sponsors some of the country's major historical and archaeological museums and research and also underwrites an active publishing program that produces *Cultura,* the country's premier cultural quarterly. The House of Ecuadoran Culture (founded in the early 1940s, with branches in many Ecuadoran cities) also sponsors cultural and historical research, publications, and special events; the National Historical Archives are a subdivision of this institution. The Ecuadoran Library "Aurelio Espinoza Polit," to the north of Quito in Chillogallo, is the country's premier library. The Central University Library, the National Library, the Pontifical Catholic University in Quito, and the Municipal Library in Guayaquil also have significant collections. Notable museums of archaeology and ethnology are located in Quito and Guayaquil.

Recreation. The Ecuadoran calendar is replete with religious and secular holidays. Some of the more important ones are not national but, rather, associated with local urban or regional traditions, such as the holidays of Quito (December 1–6), Guayaquil (October 9), and Cuenca (November 3) and the Yamor festival in Otavalo in early September. Many shops and businesses also close on Saturday afternoon and Sunday. Ecuadorans devote holiday periods to sports such as soccer (the national game), basketball, and volleyball and to picnics in the countryside, to excursions to the beach, or to socializing with family or friends. Cockfights are popular, and bullfights are occasionally held in the highlands. Glove ball is a highly popular attraction on Sunday afternoons in Quito and Ibarra. National and natural parks and preserves are relatively underused, although there is some interest in mountaineering and fishing. Many holidays are associated with particular foods or drinks, and music, live or recorded, is a part of most celebrations. Uniquely popular in Ecuador are beauty contests, which are held frequently at all levels of society throughout the country.

Press and broadcasting. Many Ecuadorans are avid readers, and they support numerous newspapers and periodicals. *El Comercio,* published in Quito, is perhaps the country's most prestigious newspaper; it provides detailed, serious coverage of political, economic, environmental, and cultural news, together with commentary by a number of well-known columnists. A wide range of points of view are expressed in other newspapers and periodicals; there is no censorship generally, but debate about the validity of Ecuador's territorial claims is strictly forbidden by the government. *Vistazo,* in Guayaquil, is the most popular magazine, covering national news events and personalities in a lively and often irreverent fashion. Radio stations include one of the oldest and most powerful transmitters

Newspapers and periodicals

in the Andes, La Voz de los Andes, which is affiliated with Evangelical Protestant missionaries but provides a diverse fare of programming. Other stations broadcast everything from international rock to local pasillos, Latin-American rhythms, and Quechua language, music, and news programs. Television stations broadcast a range of soap operas, game shows, and imported programs, along with special coverage from the United States, Venezuela, Mexico, Argentina, and elsewhere. (H.P.V./Gr.W.K.)

For statistical data on the land and people of Ecuador, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

History

PRE-SPANISH ERA

The area presently known as Ecuador had a long history before the arrival of Europeans. Pottery figures have been discovered that date from 3000 to 2500 BC. The area was to some extent a frontier, exhibiting Colombian, Peruvian, and even Mexican influences. Even possible contacts with Japan have been suggested, but these are much debated. The territory, however, was also a distinct cultural area, inhabited by a variety of linguistic groups, including the highland Cara.

By AD 1400 Ecuador was divided into several warring states. In the early 15th century the Cara nation led by the Shyri dynasty began to expand in the northern and central Sierra. At approximately the same time both the larger Chimu nation of northern coastal Peru and the growing Inca state centred in Cuzco began to exert influence and pressure.

Inca conquest

The Inca conquest of Ecuador was begun by Topa Inca Yupanqui (ruled 1471–93) and extended by his successor, Huayna Capac (ruled 1493–1525), who lived much of his later life in Tomebamba, Ecuador. Although their cultural impact was otherwise spotty, the Inca spread the use of Quechua as a lingua franca and ordered large forced migrations where resistance to their conquest was especially strong. In Ecuador it is evident that Inca rule was resented by some and supported strongly by others. Huayna Capac left the Inca empire divided between his legitimate heir Huascar, in Cuzco, and his son by an Ecuadoran Cara princess, Atahuallpa. This led to a territorial dispute, and Atahuallpa won the ensuing civil war after a major battle near Riobamba in 1532; at just about the same time, a Spanish expedition led by Francisco Pizarro appeared off the coast. Atahuallpa was executed the next year as the Spanish conquest spread. In many parts of Ecuador Inca rule was less than 50 years old, and many of the pre-Inca states still held people's allegiances. As a result the Spanish under Pizarro's lieutenant Sebastian de Belalcázar were welcomed as liberators by some when they invaded Ecuador from Peru in 1534, while stiff resistance was encountered from others, especially the local leader, Rumiñahui, who was captured by the Spanish and executed in Quito.

THE COLONIAL PERIOD

Spanish estates in the Sierra

In the mountainous Andean area of central Ecuador (the Sierra), the Spaniards established a colony of large estates worked by Indian peons. People lived in semiautonomous Indian villages or in Spanish and mestizo administrative and religious centres such as Quito, Ambato, and Cuenca. The making of rough textiles in primitive sweatshops was the only industry.

On the Pacific coastal plain (the tropical Costa), there were fewer Indians to do the work, and the area was extremely unhealthy until the advent of modern medicine. As a result, the coast was neglected during the colonial period, although there was some shipbuilding and exporting of cocoa from the port of Guayaquil. The small coastal population of mixed races, with plenty of vacant land and less coercion of labour, developed a very different culture from that of the Sierra.

On the eastern slopes between the Andes and the headwaters of the Amazon (the Oriente), recalcitrant Indians and the equatorial climate prevented settlement, and the only Spaniards who attempted to live there in any numbers were missionaries. Later, this demographic vacuum was to cause Ecuador many problems.

The country's fourth major subdivision, the Galápagos Islands, were little more than pirate nests during the colonial period; but they were to achieve world fame in the 19th century because it was there that Charles Darwin made a major portion of the observations that led to his theories on evolution and the *Origin of Species*.

The people of Quito, the Ecuadoran capital, claim that it was the scene of the first Ecuadoran patriot uprising against Spanish rule (1809). Invading from Colombia in 1822, the armies of Simón Bolívar and Antonio José de Sucre came to the aid of Ecuadoran rebels, and on May 24 Sucre won the decisive Battle of Pichincha on a mountain slope near Quito, thus assuring Ecuadoran independence.

EARLY NATIONAL HISTORY, 1830–C. 1925

Ecuador's early history as a nation was a tormented one. For some eight years it formed, together with Colombia and Venezuela, the confederation of Gran Colombia. But in 1830, after a period of protracted regional rivalries, Ecuador seceded and became a separate, independent republic.

Sierra-Costa political rivalry

Liberal-Conservative hostilities. An increasing rivalry and ideological difference between the Sierra and the Costa usually focused on the two leading cities—Quito, the capital, in the Sierra, and Guayaquil, the country's principal port. Quito was the home of a landed aristocracy, whose positions of power during this early period were based on large, semifeudal estates worked by servile Indian labour; it was (and to some extent has remained) a conservative, clerical city, resistant to changes in the status quo. Guayaquil, on the other hand, by the 19th century had become a bustling, cosmopolitan port, controlled by a few wealthy merchants. These men and those around them were influenced by 19th-century liberalism; interested in trade, they favoured free enterprise and expanding markets, and some were anticlerical. Their bourgeois attitudes conflicted sharply with the more aristocratic beliefs of the Sierra elites. These early rivalries tended to be exacerbated by the nature of the two cities. The people of Guayaquil, the nation's breadwinner and the home of Ecuador's industry and trade, felt that a disproportionate part of the state's tax income was spent in Quito by government bureaucrats. Those in Quito complained that their exports had to pass through the monopolistic bottleneck of Guayaquil, which acted as a traditional middleman and, by adding to the price of Sierra products, reduced their competitiveness in the world market.

Rivalry between Flores and Rocafuerte (1830–45). Ambitious generals and politicians have played on this Quito-Guayaquil rivalry since the foundation of the republic in 1830. During the period 1830–45 two leaders from the wars of independence—Juan José Flores and Vicente Rocafuerte—struggled for power; Flores found much of his support in Quito, Rocafuerte in Guayaquil. Hostility was not constant, and for a few years the rivals agreed to alternate in the presidency. They were not simply personalist dictators; Rocafuerte in particular had a coherent ideology of government and did much to improve the educational institutions of the main cities. Both, however, were capable of deplorable conduct in their efforts to retain or regain power. Flores, on one occasion, even invited the Spaniards to return.

Breakdown of national government (1845–60). The rivalry between Flores and Rocafuerte was a struggle between two strong leaders. Between 1845 and 1860, however, the nation went through a period of chaos in which a series of squabbling, weak leaders (usually self-proclaimed liberals) fought for the presidency. This period reinforced the already close ties between the military and the national government.

The regime of García Moreno (1860–75). In the next period (1860–75) one of Latin America's most extraordinary experiments in autocracy occurred, during the presidency of Gabriel García Moreno. As a young man García Moreno had witnessed the chaos in Ecuador and the selfish struggles of the various cliques. He had also seen the European Revolutions of 1848 and had developed an

abhorrence of liberalism and of uncontrolled violence. A careful analysis of Ecuadoran society led him to conclude that the young nation lacked unifying factors; it had no great tradition, suffered from regional resentments, and was sharply divided by class and between whites and Indians who did not even share a common language. García Moreno concluded that the only social "cement" was religion—the general adherence of the population to the Roman Catholic church. He felt that in time nationalism could be created and that more social cohesion would emerge as a result, but that meanwhile Ecuador needed a period of peace and strong government. When he became president, therefore, he based his regime on two factors—strong authoritarian personal rule and the Roman Catholic church. All education and welfare, and the direction of much government policy, were turned over to clerics. Other religions were harshly discouraged. All opposition was ruthlessly suppressed, and some leading liberals spent many years in exile.

Lack of unifying elements

Although many aspects of García Moreno's regime were reactive, it did mark the first period of genuine progress for Ecuador. Roads, schools, and hospitals were built. A start was made on a Quito-Guayaquil railroad, to tie together the Costa and the Sierra. García Moreno encouraged the planting of eucalyptus trees from Australia to combat erosion in the Sierra, where the original ground cover had been cut down for fuel by the impoverished Indians. Other agricultural reforms slowly raised production. By the end of his regime a strong feeling of nationalism had been created among the urban classes.

In the 19th century, however, this authoritarian, clerical government seemed an anachronism, and liberal opposition grew both at home and abroad. When García Moreno was assassinated on the steps of the government palace in 1875, the liberal intellectual and pamphleteer Juan Montalvo proclaimed from exile, "My pen has killed him."

Shift to liberalism (1875–97). García Moreno's death, as he himself might have forecast, brought a period of near anarchy. Conservatives and Liberals struggled for power. But Ecuador had become part of the world market; the importance of the coast slowly increased, and the Liberals of that area more and more dominated the economy.

A new Liberal hero emerged from the lower classes as the leader of the coastal reaction to Sierra conservatism and clericalism. A man of great personal magnetism, General Eloy Alfaro, led a march against the Sierra in 1895 and after a year became constitutional president, serving two terms (1897–1901 and 1906–11). Much of the administrative structure of the García Moreno era was dismantled. The anticlerical Liberals gradually removed the church from state education: they instituted civil marriage and burial, proclaimed freedom of religion, permitted divorce, and eased controls on the press. The church's tithe was abolished, and many of its large estates were confiscated by the state, some estates passing into the hands of Liberal leaders.

The reforms of Eloy Alfaro

In many ways, however, in spite of political manifestos to the contrary, the Liberals of this era shared the basic ideas of the previous period. They advanced García Moreno's road- and railroad-building programs; the Quito-Guayaquil railroad was completed in 1908 during Alfaro's second term. Moreover, central government did not lose its authoritarian caste; Alfaro, the Liberal strongman (caudillo), was as arbitrary and ruthless as his conservative predecessor. In the Sierra and on the coast, power remained unchanged. The problem of the great haciendas was not touched, and the change to liberalism meant little to the impoverished Indians and peasants.

Alfaro's overthrow, like that of García Moreno, was brought about by his stubborn attempts to perpetuate himself in office. A coalition of Conservatives and dissident Liberals forced him and his clique from the presidency in August 1911, but when the next president died in office shortly thereafter, the aging and increasingly unpopular Alfaro returned from exile and tried to recapture his following. The leaders of the Liberals rejected him, and after some fighting he was arrested in Guayaquil. He and his lieutenants were sent to a model prison in Quito, built years before by García Moreno. There, on Jan. 28, 1912, a lynch mob broke in, dragged the prisoners through the streets, and burned the bodies.

Problems of the early 20th century. The Liberals remained in office, but the real power continued to rest in the hands of the wealthy merchants and bankers of Guayaquil. During World War I and the short boom that followed it, this clique further extended its influence and diversified its capital with a view to owning the agriculture of the coastal plain. Cacao was the dominant export crop, as in the colonial period, but sugar and rice became increasingly important.

A depression followed in the early 1920s. The price of food increased, and exports in general declined. The sucre—the national unit of currency—fell rapidly in value. At the same time, the nation's cacao plantations became infected with a fungus known as witches'-broom, and production sagged. These crises brought urban discontent, the formation of trade unions in Guayaquil, riots, and massacres by the army. Hundreds died during riots and shootings in November 1922.

In 1925 the army entered this turbulent situation, claiming that it wished to restore national unity and blaming many of the country's problems on the merchant bankers of Guayaquil. Like most Latin-American revolutions, that of 1925 brought little change in social and economic structures.

MODERN HISTORY

The period between 1925 and 1948 was one of greater turbulence than Ecuador had ever known. Increasing involvement in the world market and in international politics meant that the nation could no longer escape entanglements and the consequences of world ideological conflicts. Yet during this crucial period, Ecuador's internal disunity prevented the modernization of its social structure, land tenure system, education, and communications. Thus, the country was badly equipped to face the demands of the age.

Economic development and loss of territory in the 1940s. Ecuador was still suffering from the effects of the Great Depression when it became involved in World War II. It sided with the Allies and allowed the United States to build military bases on its territory, but it played little direct part in the war. Under President Carlos Arroyo del Río, Ecuador drew some benefit from the higher prices for raw materials caused by the war, and the early years of the war were relatively prosperous and tranquil.

World War II had a serious secondary effect on the nation, however. Because of lack of capital and people, Ecuador by 1940 had not effectively settled its vast Amazonian territories. In July 1941, after long diplomatic bickering and a series of border incidents, the Peruvian army invaded, seized much of the disputed Amazonian area, and devastated El Oro *provincia* (Ecuador had lost territory to each of its more powerful neighbours during its troubled history). The Ecuadoran forces, poorly trained and equipped, were easily defeated, and the disgrace caused the overthrow of Arroyo del Río. The United States and the other major powers were too preoccupied with the war to allow such small conflicts to destroy Allied unity or to disrupt the production of vital raw materials. A peace conference in Rio de Janeiro in 1942 forced Ecuador to relinquish its claims to much of the Amazonian region. Subsequently, Ecuador repeatedly attempted to reopen the question, claiming that the Protocol of Rio was imposed by force and that the new borders were therefore invalid. This constant Ecuadoran irredentism was used repeatedly by demagogues and ultranationalists, who distracted attention and effort from urgent internal problems.

War with Peru

Domination of Velasco Ibarra (post-World War II). Politics and government after World War II presented contradictions. Ecuador enjoyed a long period of constitutional government and relatively free elections following the presidency of the Radical Liberal leader Galo Plaza (1948–52). There were also two long interludes of military government (1963–66; 1972–79), but the period was dominated by one of Latin America's great caudillos, José María Velasco Ibarra. Velasco Ibarra, who died in 1979, was president of Ecuador five times but completed only

one of these terms. He seemed able to win any election, such was his popularity with the masses, but his terms of office were marked by sudden reversals in policy, contradictory economic programs, personal outbursts, temporary suspensions of civil liberties, and military interventions. Some critics claimed that Velasco Ibarra drew support from communist groups; others said he was the puppet of powerful business groups in Guayaquil. But no group was able to control the erratic leader for long.

Impact of Velasco Ibarra's rule

Velasco Ibarra's political presence may have inhibited the development of social and economic reforms. His personal appeal cut across parties and ideologies. The traditional parties—the Liberals and the Conservatives—were thrown into disarray by his incursions, and the growth of newer parties such as the Ecuadoran Socialists and the Social Christians was retarded. Opponents alleged that Velasco Ibarra made economic progress impossible because he so frequently halted or reversed measures undertaken by previous governments.

Ecuador from the late 20th century. After Velasco Ibarra's last fall from power, in 1972, military officers ruled for some seven years before handing over the government to a constitutionally elected (July 16, 1979) civilian president. The civilian and military governments of the 1970s did not adequately manage the oil boom that occurred in that decade. The boom increased the size and wealth of the middle class, led to the building of roads, quays, pipelines, and other infrastructural features, and caused severe inflation. The poor suffered the effects of inflation but reaped few of the benefits of the oil boom.

Velasco Ibarra's death and the withdrawal of the military officers from government allowed the nation to return to an elected civilian government and a new constitution in 1979. Jaime Roldós Aguilera, a young social democrat, was elected president on a reformist platform. He promised greater social equality and a more equitable distribution of oil industry profits, but he was unable to manage the legislature and was soon at odds with his own party. His popularity increased after a border skirmish with Peru in early 1981, but he was killed in an airplane crash later that year. His successor was Osvaldo Hurtado Larrea of the small Christian Democratic party. The economy, depressed by a drop in world oil prices, spiraled downward with accompanying high inflation and a depreciating currency. León Febres Cordero, a congressman from Guayaquil, was elected president in 1984. His free-market economics and pro-U.S. foreign policy drew Ecuador into closer alliance with the U.S. administration of President Ronald Reagan, but Febres Cordero was never popular in Ecuador. Oil prices continued to fall, and his troubles with the National Congress and the military led to calls for his resignation and, on one occasion, to his being kidnapped by air force personnel for half a day until he agreed to release one of their leaders. In March 1987 he suspended interest payments on Ecuador's $8.3 billion foreign debt after an earthquake destroyed part of a major oil pipeline.

In the presidential runoff election of May 1988, a left-wing opponent, Rodrigo Borja Cevallos, was elected, but he seemed to have few solutions to the steadily worsening economic crisis. (M.J.MacL.)

Indigenous uprising of 1990

Borja's term was marked by a major indigenous uprising in June 1990, which was remarkably nonviolent. Thousands of Indians marched, blockaded roads, and occupied churches as they demanded land reform, recognition of Quichua (Quechua) as an official language, payment by oil companies for damage to indigenous lands, and support for bilingual education. The Ecuadoran government subsequently recognized indigenous land claims to much of the Oriente (but not to subsurface resources) and further promoted bilingual education.

The moderate-conservative Sixto Durán Ballén was elected president in the runoff election of July 1992. Durán eliminated most subsidies, balanced the government's budget, reduced trade barriers, brought Ecuador into the World Trade Organization, and encouraged foreign investment. These measures helped to reduce inflation, but interest rates remained high and the economy grew only slowly. A border war with Peru in early 1995 led to a standoff and proved that the Ecuadoran military had improved its capabilities; however, it left the country with a crippling war debt. Also that year, the vice president fled the country to avoid arrest on corruption charges.

Power swung to the coast in the July 1996 election when the populist leader Abdalá Bucarám Ortiz was elected president. Bucarám raised prices and became increasingly unpopular because of his seemingly erratic and controversial behaviour. In February 1997, the Congress forced Bucarám into exile and replaced him with Fabián Alarcón Rivera; voters endorsed that action in May. In early 1997 torrential El Niño rains caused major damage to the coast and further weakened the ailing Ecuadoran economy. The July 1998 elections placed Jamil Mahuad Witt, the mayor of Quito, in the presidency. In order to fight inflation, he imposed austerity measures, which were countered by public protests and demonstrations. Mahuad and President Alberto Fujimori of Peru agreed to a comprehensive delineation of the countries' long-disputed frontier; the last of the new border markers was placed in May 1999.

Dollarization

The nation's economy stagnated and its currency remained unstable. After several banks failed, Mahuad announced a plan to designate the U.S. dollar as the nation's new currency. Many groups of students, labourers, and Indians opposed the plan. Civil unrest intensified until January 2000, when a military coup deposed Mahuad and elevated Vice President Gustavo Noboa to the presidency. However, Noboa announced few initial changes to the government's policies, and the U.S. dollar became official Ecuadoran currency in September. Thousands of Ecuadorans, pressed by economic hardship, emigrated to Spain, other European nations, and the United States during the early years of the 21st century. During the same period Ecuadorans felt increasingly threatened by the escalating violence in neighbouring Colombia. (Ed.)

Edinburgh

Edinburgh (Gaelic: Dun Eideann), the capital city of Scotland, is centred near the southern shore of the Firth of Forth, an arm of the North Sea that thrusts westward into the Scottish Lowlands. The city and its immediate surroundings constitute an independent council area. The city, including the port of Leith on the Firth of Forth, lies within the historic county of Midlothian.

Physically, Edinburgh is a city of sombre theatricality, with much of this quality deriving from its setting among crags and hills and from its tall buildings and spires of dark stone. Edinburgh has been a military stronghold, the capital of an independent nation, and a centre of intellectual activity. Although it has repeatedly experienced the vicissitudes of fortune, the city has always renewed itself. Today it is the seat of the Scottish Parliament and the Scottish Executive. It remains a major centre for finance, law, tourism, education, and cultural affairs.

This article is divided into the following sections:

Physical and human geography

CHARACTER OF THE CITY

Although Edinburgh absorbed surrounding villages and the Firth of Forth ports between 1856 and 1920, its mood is still generated within the small compass of the Old Town and the New Town. The Old Town, built up in the Middle Ages when the fear of attack was constant, is huddled high on the Castle Rock overlooking the surrounding plain; the New Town, in contrast, spreads out in a magnificent succession of streets, crescents, and terraces.

"This profusion of eccentricities, this dream in masonry and living rock is not a drop-scene in a theatre," wrote Robert Louis Stevenson, the 19th-century Scottish novelist, essayist, and poet, who was born in the New Town, "but a city in the world of reality." The contrasts that make Edinburgh unique also make it typically Scottish, for, despite its reserved exterior, it is also a city capable of great warmth and, upon occasion, gaiety. Its history demonstrates that its citizens have also been capable of great passion, especially in matters royal or religious. In 1736 the burgh almost lost its royal charter following the lynching of one John Porteous, captain of the city guard. This occurrence can be viewed as a violent gesture common to the history of most old cities; yet, even in this moment of conventional madness, the city manifested its complex character: needing a hanging rope, the mob descended on a shop and bought one.

A city long renowned for a somewhat inflexible respectability—when West Princes Street Gardens were turned over to the general public in 1876, smoking was forbidden—Edinburgh concurrently maintained a fascinating netherworld of ribaldry and drunkenness. A poet or jurist of sufficient distinction might succeed in inhabiting both worlds. Such "Edinburgh characters" abounded during the flourishing neoclassical period of the 18th and 19th centuries known as the Augustan age, when the city's authors, critics, publishers, teachers, physicians, and scientists formed an intellectual elite of world influence.

(B.E./A.R.T.)

THE LANDSCAPE

Until late in the 18th century Edinburgh followed a common European pattern in continually renewing itself on its original site, but the lack of space for outward expansion compelled each successive phase to conform to the original layout. Subsequently, when expansion became possible, almost at a bound the town broke free of its medieval mold, and each further refashioning was built adjacent to, rather than on top of, its predecessor. In consequence, the soaring vertical lines of the Old Town confront the expansive horizontal ones of the Georgian New Town, and both are encircled by acres of individually distinct Victorian suburbs and finally by a ring of 20th-century urban sprawl that makes its way toward hills and sea.

Climate. Edinburgh has a mild climate. Its proximity to the sea mitigates temperature extremes. Winters are relatively warm, with average daily minimum temperatures remaining above freezing; and summers are comparatively cool, with temperatures seldom rising much above 70° F (21° C). The prevailing easterly winds are often cold but relatively dry; warmer southerly winds coming off the North Atlantic Current often bring rain. Annual precipitation is moderate, averaging 27 inches (676 millimetres), and it is evenly distributed throughout the year. Edinburgh lacks prolonged sunshine: on average for the year it receives less than one-third of the possible sunshine for its latitude. But even this is in part compensated for by its ever-changing cloudscape.

The city layout. Edinburgh now occupies some five miles (eight kilometres) of north-facing slope between the Pentland Hills and the broad estuary of the Forth River, merging there with the once-independent seaport of Leith. This slope is punctuated by upthrusts of lava; one such, called Arthur's Seat, rises some 820 feet (250 metres) and dominates the southeastern flank. The valleys between these striking hills were scoured deep and clean by glacial action in the Pleistocene Epoch. Edinburgh has been built on top of and around these obstacles so that the nearer one comes to the city centre, the more spectacular is the juxtaposition of natural and built environment, with terraces of stone confronting soaring thrust.

Castle Rock

At the city's core is the Old Town's Castle Rock, a plug of black basalt sealing the vent of an extinct volcano. It rises 250 feet from the valley floor and is crowned by the famous castle, which, subtly floodlit every night, stirs even the habituated townsfolk. Glacial ice once flowed from the west and around the Castle Rock's flanks, depositing to the east of the rock the accumulated debris of a lateral moraine—called a crag and tail formation. Along the crest

of this tail, and down its steep sides, the Old Town was built from the 11th century onward. The shortage of building space compelled it to expand skyward, and 10- and even 12-story tenements separated by narrow passageways were built in the 16th and 17th centuries.

Two hundred yards (183 metres) north of the Castle Rock, across the valley that is now Princes Street Gardens, lies the New Town, a district that was planned and built in successive phases between 1767 and 1833. It offers a dignified tribute to the international taste of the Enlightenment and to the surveyor's set square; its design was overly regular to begin with, but later developments paid more respect to natural contours and softened the regimentation of the right angle with curves and crescents. The New Town's northwestern boundary is, roughly, the line of Edinburgh's only stream, the Water of Leith. The stream's brief course from the Pentlands to the sea provided power for the mills of a series of villages—Dalry, Dean, Stockbridge, Silvermills, and Canonmills—that grew up beginning in the 16th century. The villages are now embedded in the 19th-century matrix of the town.

Expansion from the Old Town. For centuries the barrier to northward expansion was the lake and encircling marsh—the North Loch, or Nor' Loch—that choked the valley along the foot of the moraine and the Castle Rock. The lake had been created from swampland by James II as a defense against attack. Even when it was drained and the land was firmed, access to the north had to await the ability of civil engineers to span the valley with a bridge. This was achieved in 1772, when the North Bridge, 70 feet high and 1,130 feet in length and canted steeply northward, was completed.

In the centuries between the founding of the Old Town and the beginning of the New Town, Edinburgh eased itself down the southern flank of the moraine. A marketplace, known as the Grassmarket, was built in the shadow of the Castle Rock, and a roadway known as Southgate (later as Cowgate) led eastward to the Augustinian Abbey of Holyrood (later the site of the Palace of Holyroodhouse). The town then slowly climbed the facing slope of the adjacent moorland, despite the dangers inherent in exposing a southern flank to English assault. Well before the North Bridge was built, this southern suburb had grown up, dignified with fine churches—Magdalen Chapel (1544), Greyfriars (1612)—and the "Toun's College" (later the University of Edinburgh). The suburb was composed in a small-scale domestic architecture that is noticeably friendlier than the somewhat bleak facades of the New Town.

Edinburgh's bridges. In the 50 years following the building of North Bridge, four other bridges were completed, enabling the city to expand where it pleased. Two of these, South Bridge (1788) and King George IV Bridge (1834), are multiple-arch constructions that span the Cowgate ravine. These opened the way south to rapid expansion. In the same period Waterloo Bridge, with its Regency Arch (1820), opened the eastern slopes of Calton Hill (northeast of the Castle Rock) to Regency building, while King's Bridge (1833), leaping westward from the Castle Rock, was the vital link in the so-called "western approach." Throughout the Victorian and Edwardian ages the city grew in every direction, recording in its stone tenements and detached mansions every foible of changing taste—Neoclassical, Gothic, Scotch Baronial, Italianate—to spend itself in 20th-century brick and concrete. (A.R.T.)

Edinburgh Castle

The Old Town. Edinburgh Castle, 443 feet above sea level, dominates the city. The Castle Rock may have been fortified as early as the 6th century AD, but continual use of this strategic site has obliterated all material evidence of occupation before the 11th century. The principal surviving buildings have been altered to suit changing needs. They are of greater historical than architectural interest, and they date mainly from the 16th century. The small chapel of St. Margaret, the queen of Malcolm III Canmore, on the highest point of the rock, dates from the 12th century and is the oldest surviving building.

The Royal Mile

The Royal Mile, which begins outside the Castle Esplanade, descends Castle Hill, the crest of rock linking the castle with the Palace of Holyroodhouse to the east. The Royal Mile bears several names—Castle Hill, Lawnmarket, High Street, and Canongate—recalling its medieval districts. The Old Town's towering tenements are pressed together along the crest, and the cliff-face of houses is broken by wynds—narrow, winding, stone lanes leading down either side of the ridge—and closes or vennels—entryways into courtyards, around and behind which are yet more buildings.

The High Kirk

A number of important buildings are located along the Royal Mile. At its heart is the High Kirk, or Cathedral, of St. Giles, the National Church of Scotland. It has a fine late Gothic nave and is surmounted by a magnificent 15th-century crown tower, an open spire with eight flying buttresses supporting a sculptured turret. Much of the exterior stonework is a 19th-century restoration.

Behind St. Giles, in Parliament Square, is Parliament House, which was built by the Town Council during 1632–39 with the aid of private contributions when Charles I threatened to move the law courts elsewhere. The Scots Parliament met there from 1639 to 1707. The supreme civil and criminal courts of Scotland now sit in the building. The Parliament House complex is adjacent to the National Library of Scotland, successor to the earlier Advocates' Library, of which the philosopher David Hume was once librarian.

Opposite St. Giles, slightly to the east, is the City Chambers. The building was completed in 1761 as the Royal Exchange but never was used for that purpose. It faces the Mercat Cross (Market Cross), the hub of the old city. Part of the original pillar of the Cross was used in a late 19th-century reconstruction undertaken at the expense of Prime Minister William Gladstone. Royal proclamations are announced from its tower platform by members of the Court of Lord Lyon (the Scottish equivalent of the College of Heralds).

Almost opposite the Tron Kirk, where all incoming goods once passed over an iron scale ("tron"), and where the North and South bridges cut across the crest, is Anchor Close, where William Smellie, printer to the University of Edinburgh and editor of the first edition of the *Encyclopædia Britannica,* printed the 1787 edition of the *Poems* of Robert Burns. Smellie introduced Burns to the conviviality of a club called the Crochallan Fencibles; the poet, in return, regaled them with the bawdy songs entitled *Merry Muses of Caledonia* (first published in 1800).

Noteworthy buildings along the High Street and Canongate sections of the Royal Mile include the John Knox House, built in the late 15th or early 16th century; Moray House, a 17th-century town house now used as a teacher-training college; the baroque-fronted Canongate Church (1688–90), in the graveyard of which are the tombs of Robert Fergusson, an 18th-century poet, and the political economist Adam Smith; Acheson House (1633), containing the Scottish Craft Centre; Huntly House (containing the Civic Museum); and the old Canongate Tolbooth (1591). The 17th-century inn in White Horse Close, once the terminus of the London coach, has been splendidly restored as private homes.

Holyrood. Away from the crowded buildings, at the lower end of the Royal Mile, is Holyrood. The abbey was founded in 1128 and rebuilt about 1220. The ruins of the nave are impressive examples of the bold, imaginative work of the period. The Palace of Holyroodhouse, which shouldered the abbey aside, comprises an early 16th-century wing and a 17th-century quadrangle court and facing wing. It is the sovereign's official residence in Scotland. South and east of the palace is Holyrood Park, which includes the Salisbury Crags and Arthur's Seat as well as three lochs.

The floral clock

Princes Street Gardens. The Princes Street Gardens, laid out between the Old and New towns in the drained lakebed of the old North Loch, have a distinct character. Flowers are set out in beds changed several times a year, and a floral clock planted in 1903 (the first in the world), which embowers a quarter-hour cuckoo, has some 24,000 plants in its 36-foot circumference. Among the lawns, flower beds, and groves are recreational areas, a bandstand, an outdoor dance floor, and numerous memorials, the most conspicuous of which is an 1844 Gothic spire,

200 feet high, that rises above a statue of Sir Walter Scott and his hound, Maida.

For the first 100 years of its existence, West Princes Street Gardens was the private amenity of Princes Street proprietors. In 1876 this tract was opened to the public, which had always had access to the eastern gardens. The Mound, a causeway of rubble and earth from New Town construction, forms the division between the two gardens. On the Mound stand two neo-Grecian temples to the arts: the Royal Scottish Academy (1832) and the National Gallery of Scotland (1859). Railroad tracks—now almost concealed by landscaping—were laid through the middle of the gardens in 1847, and trains bound for Glasgow and the north pass under the Mound. The rails terminate in the east end of the park at Waverley Station.

The New Town. The town council approved plans for the New Town in 1767. It was designed to be a residential district. The architect, James Craig, set out a grid five streets deep and seven streets wide, its broad central axis terminating in grand squares at each end. St. George's Church would anchor the western end of the scheme, St. Andrew's the eastern. Princes Street, the southernmost of the new streets, was lined only on its north side with residences, which faced the castle across the valley. The arrival of the railway changed the face of Princes Street as residential space gave way to shops and hotels. Princes Street became the main shopping street and the principal thoroughfare of the city, and few original buildings remain behind the shop fronts. The Register House (1772–92), at the east end of Princes Street facing the North Bridge, is the finest of the city's buildings by the 18th-century architects James and Robert Adam. It houses part of the national records of Scotland. In the remainder of Craig's New Town much has been done to restore and improve the amenity of the streets and squares. In St. Andrew Square the Royal Bank of Scotland, built as a town house in 1772–74 for Sir Lawrence Dundas when he was the member of Parliament for Edinburgh, is a fine example of an 18th-century mansion and has a stunning Victorian banking hall (1858). In George Street is the parish church of St. Andrew, an oval building with a fine plaster ceiling and an elegant spire. On the north side of Charlotte Square the Georgian House, managed as a museum by the National Trust for Scotland, is completely furnished, from kitchen to bedrooms, with all the appurtenances of late 18th-century Edinburgh elegance.

At the east end of Princes Street the Calton Hill rises above the central government office of St. Andrew's House (1937) and the adjacent Royal High School (1825–29). It is crowned by the 19th-century architect William Playfair's City Observatory (1818) and a charming Gothic house, by Craig, built for the astronomer royal. Behind this rise 12 columns of an intended replica of the Parthenon, designed by Playfair in 1822 as a memorial to the Scots who died in the Napoleonic wars. Construction of the memorial was abandoned when the subscription failed in 1830. Down the slope to the south stands the tiered circular tower of the Nelson Monument (1807).

To the north, on the flat plain toward the Forth, the Royal Botanic Garden, at its finest when the great rhododendrons are in bloom, offers from its crest a superlative vista of the New Town backed by the distinctive skyline of the Old Town.

THE PEOPLE

Edinburgh's population is largely a mixture of middle-class professionals and nonprofessionals. Both have achieved a measure of prosperity as compared with their ancestors, most of whom emigrated from the surrounding countryside and small towns to provide the 19th-century city with unskilled and semiskilled labour. The work force has changed considerably since then, and now white-collar workers equal blue-collar workers in number. The city has only a small percentage of people from other countries; according to the 1981 census, less than 5 percent of the city's population was born outside of the United Kingdom.

THE ECONOMY

Industry. Edinburgh is today, as it was in the 18th century, predominantly a provider of services. Barely one-tenth of its residents are now in manufacturing. The pre-World War II staples of brewing, baking, and book printing have all suffered. Electrical and electronic research and engineering, much of it related to defense and much of it drawing on the scientific skills of the town's two universities, has become the largest industrial employer.

The main service industries are related to public administration, the law, medicine, investment and finance, education, and tourism: Edinburgh is second only to London as a British tourist city. The regional and district councils of local government constitute the largest employer, with education also of major importance.

The port of Leith, about 30 miles from the open sea, became a part of the six-port Forth Ports Authority in 1968 and was extensively modernized in the 1970s. Grain, foodstuffs, and wood products are the principal incoming products; outbound shipments consist of coal, whisky, iron, and steel. Granton, Edinburgh's other port town, is also under the authority, with special facilities for rapid loading and unloading; a sizable industrial estate to service North Sea petroleum has been developed there, and it is the home port for the Firth of Forth fishing fleet.

Commerce and finance. Edinburgh is an important centre for financial and legal services. The city's institutions financed much of the development of the American West, including ranching, railroads, timber, and mining, and thereby laid the basis for its fortune. As the centre of Scotland's legal system, Edinburgh has a flourishing legal

A.G. Ingram Ltd., Edinburgh

Princes Street, showing Castle Rock overlooking the city, the Scott Monument (foreground), the National Gallery of Scotland, and the Royal Scottish Academy, Edinburgh.

profession, which ranks second only to banking as the highest paid profession in the city.

Transportation. The city is served by ScotRail, the regional rail carrier. There is frequent train service to London and the major Scottish cities as well as regular service to other parts of Scotland and England. Edinburgh has two central railway stations: Waverley (the second largest in Britain) and Haymarket. Edinburgh's airport has no direct transatlantic service but does offer international service to continental Europe. The city has no subway system but has excellent bus service.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. The Scottish Parliament is responsible for legislation concerning health, education, housing, economic development, regional transport, the environment, and agriculture. The leading parliamentary party elects a first minister, who heads the Scottish Executive, which implements Scottish legislation. Directly below the Scottish government is the popularly elected City of Edinburgh Council, which implements Scottish laws at the local level. It oversees services such as local planning, education, social services, housing, roadways and traffic, fire fighting, sanitation, housing, parks and recreation, libraries, city museums, and elections.

A decline in social service funding has been partly compensated for by volunteer organizations. Relatively high youth unemployment, as well as a lack of entertainment or recreational amenities (especially in some post-World War II suburbs), has made the city notorious for drug abuse, petty violence, and more serious crime.

Health. Even before the foundation of the Edinburgh faculty of medicine in 1726, the healing arts were both practiced and taught in the city. With the opening of the great new Royal Infirmary in 1748, however, Edinburgh became one of the chief medical centres in the world. Today the city has more than 10 hospitals. Edinburgh's medical community offers a range of health services unsurpassed anywhere in the United Kingdom.

An international medical centre

Education. The City of Edinburgh maintains a system of state schools that provide free primary and secondary education. The city also provides free nursery schools and schools for children with special needs as well as a program of community education for youth and adults. Edinburgh also has several fee-paying independent schools.

The University of Edinburgh, founded in 1583, is the city's largest university. A world-renowned intellectual centre for much of its history, it offers a range of undergraduate, postgraduate, and professional programs. Heriot-Watt University, dating from the earliest days of the Industrial Revolution, was one of the first of Britain's new technological universities. Much of its operation has been transferred to a satellite campus outside the city centre at Riccarton. Jewel and Esk Valley College offers a range of postsecondary vocational courses. The Edinburgh College of Art offers courses in the fine arts and various aspects of environmental design, including architecture, landscape architecture, and city and regional planning.

CULTURAL LIFE

Since 1947 Edinburgh has been an international focal point for the arts during the three weeks of its annual summer festival. The original Edinburgh International Festival now occurs concurrently with both the Edinburgh Festival Fringe, which features avant-garde and innovative performances, and the Edinburgh International Film Festival. Hundreds of thousands of visitors come for the theatre, ballet, music, films, art expositions, and the general excitement, which closes with a skirl of the Scottish bagpipes before the castle gate. A major cultural institution is the National Galleries of Scotland. It includes the National Gallery, with a fine international collection of art as well as a representative collection of Scottish painters. Under the direction of the National Galleries are the Scottish National Portrait Gallery and the Scottish National Gallery of Modern Art, which has a good collection of French Impressionist works.

The city has a large number of recreational facilities. In addition to spectator sport venues, it has within its boundaries 9 miles (14 kilometres) of coastline for boating, several beaches, and numerous golf courses. Indeed, golf has been played in Edinburgh since 1457. There are also scores of bowling greens, public association football (soccer) and hockey fields, cricket pitches, tennis courts, putting greens, and short-hole golf courses. The Meadowbank Sports Centre, just east of the city centre, has facilities for more than 30 sports. The Royal Commonwealth Pool is one of the finest in the United Kingdom. The city is home to the Hibernian and the Heart of Midlothian football clubs.

History

THE EARLY PERIOD

Settlement of the region. To the first settlers in Scotland, arriving in the early postglacial period as early as 7000 BC, estuaries and rivers offered the best access to the interior; and of these the Forth was among the most important. Its shoreline and mudflats show evidence of Stone Age explorers, who as yet had no need for the protection of the region's steep hills. Finds of swords and other metal objects suggest, however, that by about 1500 BC these Celtic tribes were making use of the crags of Arthur's Seat for defense. In the Iron Age, which in Scotland began in about 800 BC, hill forts proliferated in the Lothians—the area in the immediate vicinity of Edinburgh—and the Borders, to the south. There is no proof that the Castle Rock was occupied at that time, but it is unlikely that so good a defensive site would have been ignored. Holyrood Park, Blackford Hill, and Craiglockhart Hill, however, all bear witness to occupation in the late 1st millennium BC.

Strategic importance. The Romans viewed the Edinburgh plain between the Pentland Hills and the Forth as being of strategic rather than defensive value. During three or four decades in the second half of the 2nd century AD, the Antonine Wall, stretching across Scotland between the Clyde River and the Firth of Forth, was the northernmost defense in Roman Britain, and the site of Cramond, a village on the Forth within the modern city boundary, was the point at which one of Roman Britain's major north–south roads terminated. The road, with major forts at Dalkeith and Inveresk on the southeastern approaches to the present city, cut through what is now the Meadows district of Edinburgh and guarded access to the Carse (river valley) of Stirling and the approach to the west and north.

If at this time the Castle Rock site was occupied, it would have been by the Wotadini (Votadini), the dominant Celtic tribe of the Lothians, with whom Rome had a relatively stable relationship. The Wotadini capital was on Traprain Law, a cone-shaped hill ("law") some 20 miles east of the modern city; but it appears that in about AD 500, after the Roman withdrawal from Britain, the capital was moved to the site of the present Castle. A poem composed in about AD 600 tells how a band of the Gododdin (an alternative form of Wotadini), from around a place called Din Eidyn, attacked an Anglian force at Catterick in Yorkshire and was annihilated. Din Eidyn—"Eidyn's Hill Fort"—is clearly the Castle Rock site. In the following centuries the Gododdin seem to have been vanquished by Anglian invaders, and by AD 854 Din Eidyn (also spelled Duneideann) had become Edwinesburh (*burh* meaning "stronghold"), giving rise to the supposition that the town was founded by a Northumbrian princeling called Edwin. The date of the poem disproves this, however; it can reasonably be asserted that the Castle Rock site has been continuously occupied for at least 1,400 years, but little is known of the town's earliest centuries.

The Wotadini

THE MEDIEVAL CITY

Mercantile growth. From the mid-11th to the mid-12th century St. Margaret's chapel in the Castle Rock and the Abbey of the Holyrood, endowed by Margaret's son King David I, marked the limits of the Old Town, with the parish church of St. Giles between. In 1130 David I granted Edinburgh the status of a burgh, a privilege

that promoted trade by allowing Edinburgh to act both as a market and as a centre for organized manufacture (particularly of cloth). When David instituted the earliest Scottish coinage, the mint was situated in Edinburgh. He also granted the monks (canons) of Holyrood leave to have their own burgh—with their own jurisdiction; this came to be known as the Canongate. The High Street of Edinburgh ended, and the Canongate began, at the intersection called Netherbow.

Political importance. In 1329 King Robert the Bruce granted Edinburgh a town charter, and its subsequent emergence as the political centre of the nation paralleled its mercantile growth. Perth, a major settlement to the north, had for a time contended for the position of royal capital, but after 1436 Edinburgh's claim was upheld, despite its vulnerability to English invasions. James II (1430–60) was crowned in Holyrood, and most of his parliaments were held in the city (on the site, adjacent to St. Giles, where the Tolbooth was erected in 1466). By the reign of James III (1460–88), Edinburgh was actually described in a royal charter as "the principal burgh of our kingdom" and its established capital.

The medieval burgh—churches and royal and civic buildings apart—was built of wood, and only the houses of the well-to-do had glazed windows and wooden doors. All domestic refuse and the offal of the skinners, butchers, and fishmongers were heaped on either side of the main street, forcing pedestrians to keep to the centre of the street. The graveyards—including that of St. Giles, in the town centre—were used as rubbish dumps. That Edinburgh was uncommonly nasty in this respect was largely the result of its physical setting and the absence of a water supply: until 1681 water had to be fetched from pumped wells south of the Canongate. William Dunbar (*c.* 1460–*c.* 1520), the great Middle Scots poet, wrote in trenchant verse:

> May nane pass through your principal gates
> for stink of haddocks and of skates,
> for cries of carlings [old women] and debates [arguments]...
> tailors, souters [shoemakers], and craftis vile
> the fairest of your streets does fyle [defile]...

To the moderate prosperity of the late medieval burgh, King James IV (1473–1513) added a touch of European Renaissance culture. He patronized the arts, established in the town the supreme court of justice, and in about 1501 began the construction of a palace at Holyrood, of which only the gatehouse survives. In 1507 in the Cowgate, at the prompting of Bishop Elphinstone, he encouraged the establishment of Scotland's first printing business. In the years of political unrest following the disastrous defeat of the Scots by the English at Flodden in Northumberland (1513), Edinburgh encircled the Old Town (as far as the Netherbow) with a defensive wall, parts of which still stand. It proved sadly ineffective, however, as was shown in 1544 when an English commander, the Earl of Hertford, devastated the entire town, including Canongate and Leith.

Although much of the subsequent rebuilding was still in wood, it was from this period and after that stone became more common, both for public buildings and for the residences of the wealthy. Edinburgh's position made it the seat not only of the court but also of the Privy Council, Parliament, and the law. The great landed families began to keep town houses in the Canongate, and their patronage, frequently more munificent than that of the indigent House of Stuart, stimulated the local economy. Thus, Edinburgh gradually recovered some of the economic and cultural importance lost after Flodden. The Royal College of Surgeons had been founded in 1505. In 1535 the College of Justice was endowed by the church (still at this stage Roman Catholic). And after the young King James VI established himself at Holyrood, he attempted to open Edinburgh up to European culture. In 1582 he granted the town council a charter encouraging the provision of buildings to house the teaching of "humanity, philosophy, theology, medicine, and laws, or of any other liberal sciences whatsoever." This stimulated the foundation of what is today the University of Edinburgh.

Growth in reign of James VI

Disaster and recovery. After 1603, when James VI succeeded to the English throne as James I of England and left for the south, Edinburgh suffered a decline in political and cultural terms, yet the town continued to grow. The first Edinburgh girls' school, the Merchant Maiden Hospital, was opened in 1605, and construction of Heriot's Hospital, a school endowed by the goldsmith and moneylender George Heriot, was begun in 1628. Parliament House, on the site of St. Giles's burying ground, was completed in 1639.

By this time, the area around St. Giles had become the centre of the capital's bustling life. Immediately to the west of the church stood the Tolbooth, combining the roles of council chamber, jail, and place of execution. To the south was the Parliament House and embryonic Parliament Close, with the Court of Exchequer; to the north, the narrow tenement called the Luckenbooths, with its street-level shops. Around the church walls were the *kames*, wooden booths of goldsmiths, jewelers, stationers, and craftsmen. To the east was the Mercat Cross, where business was done from morning to evening.

UNION WITH ENGLAND

Throughout the 17th century the Scottish economy became a weaker relative to England's. In the closing decades of the century, Edinburgh became the head office of an enterprise aimed at establishing a free port at Darién on the Isthmus of Panama, manned by Scots colonists. The scheme failed, however, and by the early 18th century union with England—and thus freedom to trade in the English colonial markets—seemed the last hope of economic growth. In 1707 the Act of Union was signed in a cellar in Parliament Square, and Edinburgh lost all independent political life.

The opportunities for increased trade with a British common market of 7,000,000 people in fact offered little advantage to Edinburgh, for it had no staple manufacture. Yet in the first half of the 18th century it doubled its population and increased its wealth. An observer of 1793 wrote of how "a perpetual influx of the unemployed from the north press into Edinburgh."

Despite the overcrowded conditions in the Old Town, the union brought about a surge of rebuilding and new building within its walls. Much of Parliament Square, badly damaged by fire in 1700, was restored by 1715. New tenement courts were built in the Lawnmarket in the 1720s; the first infirmary (hospital) was opened in 1729, and then a splendid custom-built building was erected in 1748. In the 1730s George Watson's Hospital (a great rival of Heriot's school) was endowed, and in the early 1750s the Royal Exchange (near the City Chambers) was built on the north side of the High Street at the Mercat Cross. It was only after the construction of North Bridge that development took place on a large scale beyond the confines of the Old Town.

Several decades earlier, in the 1720s, the town had reformed and developed its university on the faculty system (the medical faculty was instituted in 1726). This change made possible Edinburgh's contribution to that extraordinary intellectual and cultural flowering known as the Scottish Enlightenment. The Edinburgh Enlightenment itself was very much an Old Town affair. A characteristic of Old Town life was that each multistoried building housed a cross section of Edinburgh society: the very poor at street level or up in the attics; the wealthy on the main floor above street level; and others in between, according to a system whereby the lower the income the less desirable the floor occupied. All shared a common stair and ate and drank in common at the same taverns. Something of this commonness—plainness as well as coarseness—was apparent in Edinburgh's outbreak of intellectual inquiry: a strong, broad, confident ability to grasp the first principles of things and to explain them in the common language, preferably through conversation and debate. So David Hume grasped that there were no uncaused events; Adam Smith recognized the implications of division of labour; Adam Ferguson the danger of "alienation" inherent in labour; William Robertson the degree to which environmental factors shaped economic history; Joseph Black the principle of latent heat; and James Hutton the enormous antiquity of the Earth. As well as these, Edin-

The Edinburgh Enlightenment

burgh was the university of the poet James Thomson; of James Boswell, the biographer of Dr. Johnson; the novelist and poet Oliver Goldsmith; the jurist and writer Lord Kames; the French novelist Benjamin Constant; and Benjamin Rush, an American signatory of the Declaration of Independence.

Toward the end of the 18th century those able to afford the price of a house in the New Town deserted the Old Town. For the first time in five centuries Edinburgh became socially segregated, and, in the political climate of the French Revolution, the city's intellectual elite became authoritarian and antiradical. For 30 years into the 19th century Edinburgh continued to dominate the literary world in Britain, with Sir Walter Scott as its greatest figure, but, by the beginning of Queen Victoria's reign, Edinburgh's intellectual fervour had subsided. The pace of social segregation slowed as well in 1833, when the Town Council, which had sponsored the building of the New Town, went bankrupt.

THE MODERN CITY

From about 1830 until World War I, Edinburgh developed as an industrial centre. A huge growth in the labouring population resulted in severe problems of overcrowding, malnutrition, and epidemics. The city's industries included baking, brewing, distilling, book printing, wire drawing, coach building, and the manufacture of machinery for paper mills along the Water of Leith and the north Esk. The chemical, pharmaceutical, and rubber industries flourished later.

In the 1920s and '30s Edinburgh was at the centre of the Scottish political and literary renaissance led by the nationalist poet Hugh MacDiarmid (pseudonym of Christopher Grieve). Many writers joined in his attempt to revitalize the Lowland Scottish dialect as a literary language. Edinburgh has, since 1930, and particularly since the 1960s, grown more conscious of its Scottish individuality and outlook, seeing this not as parochial and inward-turned but as much more European than the relative isolationism of English culture.

Edinburgh's revival

Four aspects of post-World War II Edinburgh are noteworthy. First is the great expansion of higher education. Since the late 1920s the University of Edinburgh has grown to establish itself as a world leader in areas of advanced research such as medicine and surgery, electronics, and artificial intelligence. Second, the cultural life of the city has expanded, and, although it found major expression in the Edinburgh International Festival, initiated in 1947, firm roots also have been put down in more local enterprises such as the Traverse Theatre, the Demarco art gallery, the restoration by the University of Edinburgh of St. Cecilia's Hall in Cowgate as a small concert hall, the creation of the Scottish Baroque Ensemble, the opening of the Scottish National Gallery of Modern Art, and the conversion of Hope Park Chapel into a home for the Scottish Chamber Orchestra. Literature also has flourished. Small individual publishing firms with an international outlook and a commitment to Scottish writing have reemerged. Third, the city has become acutely conscious of its own heritage in stone and has mounted a strong conservation movement. Local bodies such as the Cockburn and Georgian societies have combined with bodies such as the National Trust for Scotland, the Royal Fine Art Commission, and the Royal Commission on Ancient and Historical Monuments to ensure that the best of the old is preserved and restored and that the worst of the new—including both traffic flow and office blocks—is prevented from intruding into the heart of the city. Finally, Edinburgh has resumed its place as an autonomous political centre. With the establishment of a new Scottish Parliament and government in Edinburgh in 1999, the city has returned to a role as not only the cultural centre but also the political centre of Scotland.

Edison

Thomas Alva Edison was the quintessential American inventor in the era of Yankee ingenuity. He began his career in 1863, in the adolescence of the telegraph industry, when virtually the only source of electricity was primitive batteries putting out a low-voltage current. Before he died, in 1931, he had played a critical role in introducing the modern age of electricity. From his laboratories and workshops emanated the phonograph, the carbon-button transmitter for the telephone speaker and microphone, the incandescent lamp, a revolutionary generator of unprecedented efficiency, the first commercial electric light and power system, an experimental electric railroad, and key elements of motion-picture apparatus, as well as a host of other inventions. Singly or jointly he held a world-record 1,093 patents. In addition, he created the world's first industrial-research laboratory.

Edison demonstrating his tinfoil phonograph, photograph by Mathew Brady, 1878.

Born in Milan, Ohio, on Feb. 11, 1847, Edison was the seventh and last child—the fourth surviving—of Samuel Edison, Jr., and Nancy Elliot Edison. At an early age he developed hearing problems, which have been variously attributed but were most likely due to a familial tendency to mastoiditis. Whatever the cause, Edison's deafness strongly influenced his behaviour and career, providing the motivation for many of his inventions.

Early years. In 1854 Samuel Edison became the lighthouse keeper and carpenter on the Fort Gratiot military post near Port Huron, Mich., where the family lived in a substantial home. Alva, as the inventor was known until his second marriage, entered school there and attended sporadically for five years. He was imaginative and inquisitive, but because much instruction was by rote and he had difficulty hearing, he was bored and was labeled a misfit. To compensate, he became an avid and omnivorous reader. Edison's lack of formal schooling was not unusual. At the time of the Civil War the average American had attended school a total of 434 days—little more than two years' schooling by today's standards.

In 1859 Edison quit school and began working as a trainboy on the railroad between Detroit and Port Huron. Four years earlier, the Michigan Central had initiated the commercial application of the telegraph by using it to control the movement of its trains, and the Civil War brought a vast expansion of transportation and communication. Edison took advantage of the opportunity to learn telegraphy and in 1863 became an apprentice telegrapher.

Messages received on the initial Morse telegraph were inscribed as a series of dots and dashes on a strip of paper that was decoded and read, so Edison's partial deafness was no handicap. Receivers were increasingly being equipped with a sounding key, however, enabling telegraphers to "read" messages by the clicks. The transformation of telegraphy to an auditory art left Edison more and more disadvantaged during his six-year career as an itinerant telegrapher in the Midwest, the South, Canada, and New England. Amply supplied with ingenuity and insight, he devoted much of his energy toward improving the inchoate equipment and inventing devices to facilitate some of the tasks that his physical limitations made difficult. By January 1869 he had made enough progress with a duplex telegraph (a device capable of transmitting two messages simultaneously on one wire) and a printer, which converted electrical signals to letters, that he abandoned telegraphy for full-time invention and entrepreneurship.

Early inventions

Edison moved to New York City, where he initially went into partnership with Frank L. Pope, a noted electrical expert, to produce the Edison Universal Stock Printer and other printing telegraphs. Between 1870 and 1875 he worked out of Newark, N.J., and was involved in a variety of partnerships and complex transactions in the fiercely competitive and convoluted telegraph industry, which was dominated by the Western Union Telegraph Company. As an independent entrepreneur he was available to the highest bidder and played both sides against the middle. During this period he worked on improving an automatic telegraph system for Western Union's rivals. The automatic telegraph, which recorded messages by means of a chemical reaction engendered by the electrical transmissions, proved of limited commercial success, but the work advanced Edison's knowledge of chemistry and laid the basis for his development of the electric pen and mimeograph, both important devices in the early office machine industry, and indirectly led to the discovery of the phonograph. Under the aegis of Western Union he devised the quadruplex, capable of transmitting four messages simultaneously over one wire, but railroad baron and Wall Street financier Jay Gould, Western Union's bitter rival, snatched the quadruplex from the telegraph company's grasp in December 1874 by paying Edison more than $100,000 in cash, bonds, and stock, one of the larger payments for any invention up to that time. Years of litigation followed.

Menlo Park. Although Edison was a sharp bargainer, he was a poor financial manager, often spending and giving away money more rapidly than he earned it. In 1871 he married 16-year-old Mary Stilwell, who was as improvident in household matters as he was in business, and before the end of 1875 they were in financial difficulties. To reduce his costs and the temptation to spend money, Edison brought his now-widowed father from Port Huron to build a 2½-story laboratory and machine shop in the rural environs of Menlo Park, N.J.—12 miles south of Newark—where he moved in March 1876. Accompanying him were two key associates, Charles Batchelor and John Kruesi. Batchelor, born in Manchester in 1845, was a master mechanic and draftsman who complemented Edison perfectly and served as his "ears" on such projects as the phonograph and telephone. He was also responsible for fashioning the drawings that Kruesi, a Swiss-born machinist, translated into models.

Financial problems

Edison experienced his finest hours at Menlo Park. While experimenting on an underwater cable for the automatic telegraph, he found that the electrical resistance and conductivity of carbon (then called plumbago) varied according to the pressure it was under. This was a major theoretical discovery, which enabled Edison to devise a "pressure relay" using carbon rather than the usual mag-

nets to vary and balance electric currents. In February 1877 Edison began experiments designed to produce a pressure relay that would amplify and improve the audibility of the telephone, a device that Edison and others had studied but which Alexander Graham Bell was the first to patent, in 1876. By the end of 1877 Edison had developed the carbon-button transmitter that is still used in telephone speakers and microphones.

Edison invented many items, including the carbon transmitter, in response to specific demands for new products or improvements. But he also had the gift of serendipity: when some unexpected phenomenon was observed, he did not hesitate to halt work in progress and turn off course in a new direction. This was how, in 1877, he achieved his most original discovery, the phonograph. Because the telephone was considered a variation of acoustic telegraphy, Edison during the summer of 1877 was attempting to devise for it, as he had for the automatic telegraph, a machine that would transcribe signals as they were received, in this instance in the form of the human voice, so that they could then be delivered as telegraph messages. (The telephone was not yet conceived as a general, person-to-person means of communication.) Some earlier researchers, notably the French inventor Léon Scott, had theorized that each sound, if it could be graphically recorded, would produce a distinct shape resembling shorthand, or phonography ("sound writing"), as it was then known. Edison hoped to reify this concept by employing a stylus-tipped carbon transmitter to make impressions on a strip of paraffined paper. To his astonishment, the scarcely visible indentations generated a vague reproduction of sound when the paper was pulled back beneath the stylus.

The phonograph

Edison unveiled the tinfoil phonograph, which replaced the strip of paper with a cylinder wrapped in tinfoil, in December 1877. It was greeted with incredulity. Indeed, a leading French scientist declared it to be the trick device of a clever ventriloquist. The public's amazement was quickly followed by universal acclaim. Edison was projected into worldwide prominence and was dubbed the Wizard of Menlo Park, although a decade passed before the phonograph was transformed from a laboratory curiosity into a commercial product.

Another offshoot of the carbon experiments reached fruition sooner. Samuel Langley, Henry Draper, and other American scientists needed a highly sensitive instrument that could be used to measure minute temperature changes in heat emitted from the Sun's corona during a solar eclipse along the Rocky Mountains on July 29, 1878. To satisfy those needs Edison devised a "microtasimeter" employing a carbon button. This was a time when great advances were being made in electric arc lighting, and during the expedition, which Edison accompanied, the men discussed the practicality of "subdividing" the intense arc lights so that electricity could be used for lighting in the same fashion as with small, individual gas "burners." The basic problem seemed to be to keep the burner, or bulb, from being consumed by preventing it from overheating. Edison thought he would be able to solve this by fashioning a microtasimeter-like device to control the current. He boldly announced that he would invent a safe, mild, and inexpensive electric light that would replace the gaslight.

The electric light

The incandescent electric light had been the despair of inventors for 50 years, but Edison's past achievements commanded respect for his boastful prophecy. Thus, a syndicate of leading financiers, including J.P. Morgan and the Vanderbilts, established the Edison Electric Light Company and advanced him $30,000 for research and development. Edison proposed to connect his lights in a parallel circuit by subdividing the current, so that, unlike arc lights, which were connected in a series circuit, the failure of one light bulb would not cause a whole circuit to fail. Some eminent scientists predicted that such a circuit could never be feasible, but their findings were based on systems of lamps with low resistance—the only successful type of electric light at the time. Edison, however, determined that a bulb with high resistance would serve his purpose, and he began searching for a suitable one.

He had the assistance of 26-year-old Francis Upton, a graduate of Princeton University with an M.A. in science. Upton, who joined the laboratory force in December 1878, provided the mathematical and theoretical expertise that Edison himself lacked. (Edison later revealed, "At the time I experimented on the incandescent lamp I did not understand Ohm's law." On another occasion he said, "I do not depend on figures at all. I try an experiment and reason out the result, somehow, by methods which I could not explain.")

By the summer of 1879 Edison and Upton had made enough progress on a generator—which, by reverse action, could be employed as a motor—that Edison, beset by failed incandescent lamp experiments, considered offering a system of electric distribution for power, not light. By October Edison and his staff had achieved encouraging results with a complex, regulator-controlled vacuum bulb with a platinum filament, but the cost of the platinum would have made the incandescent light impractical. While experimenting with an insulator for the platinum wire, they discovered that, in the greatly improved vacuum they were now obtaining through advances made in the vacuum pump, carbon could be maintained for some time without elaborate regulatory apparatus. Advancing on the work of Joseph Wilson Swan, an English physicist, Edison found that a carbon filament provided a good light with the concomitant high resistance required for subdivision. Steady progress ensued from the first breakthrough in mid-October until the initial demonstration for the backers of the Edison Electric Light Company on December 3.

It was, nevertheless, not until the summer of 1880 that Edison determined that carbonized bamboo fibre made a satisfactory material for the filament, although the world's first operative lighting system had been installed on the steamship *Columbia* in April. The first commercial land-based "isolated" (single-building) incandescent system was placed in the New York printing firm of Hinds and Ketcham in January 1881. In the fall a temporary, demonstration central power system was installed at the Holborn Viaduct in London, in conjunction with an exhibition at the Crystal Palace. Edison himself supervised the laying of the mains and installation of the world's first permanent, commercial central power system in lower Manhattan, which became operative in September 1882. Although the early systems were plagued by problems and many years passed before incandescent lighting powered by electricity from central stations made significant inroads into gas lighting, isolated lighting plants for such enterprises as hotels, theatres, and stores flourished—as did Edison's reputation as the world's greatest inventor.

The world's first electric lighting system

One of the accidental discoveries made in the Menlo Park laboratory during the development of the incandescent light anticipated the British physicist J.J. Thomson's discovery of the electron 15 years later. In 1881–82 William J. Hammer, a young engineer in charge of testing the light globes, noted a blue glow around the positive pole in a vacuum bulb and a blackening of the wire and the bulb at the negative pole. This phenomenon was first called "Hammer's phantom shadow," but when Edison patented the bulb in 1883 it became known as the "Edison effect." Scientists later determined that this effect was explained by the thermionic emission of electrons from the hot to the cold electrode, and it became the basis of the electron tube and laid the foundation for the electronics industry.

Edison had moved his operations from Menlo Park to New York City when work commenced on the Manhattan power system. Increasingly, the Menlo Park property was used only as a summer home. In August 1884 Edison's wife, Mary, suffering from deteriorating health and subject to periods of mental derangement, died there of "congestion of the brain," apparently a tumour or hemorrhage. Her death and the move from Menlo Park roughly mark the halfway point of Edison's life.

The Edison Laboratory. A widower with three young children, Edison, on Feb. 24, 1886, married 20-year-old Mina Miller, the daughter of a prosperous Ohio manufacturer. He purchased a hilltop estate in West Orange, N.J., for his new bride and constructed nearby a grand, new laboratory, which he intended to be the world's first true research facility. There, he produced the commercial phonograph, founded the motion-picture industry, and

developed the alkaline storage battery. Nevertheless, Edison was past the peak of his productive period. A poor manager and organizer, he worked best in intimate, relatively unstructured surroundings with a handful of close associates and assistants; the West Orange laboratory was too sprawling and diversified for his talents. Furthermore, as a significant portion of the inventor's time was taken up by his new role of industrialist, which came with the commercialization of incandescent lighting and the phonograph, electrical developments were passing into the domain of university-trained mathematicians and scientists. Above all, for more than a decade Edison's energy was focused on a magnetic ore-mining venture that proved the unquestioned disaster of his career.

The first major endeavour at the new laboratory was the commercialization of the phonograph, a venture launched in 1887 after Alexander Graham Bell, his cousin Chichester, and Charles Tainter had developed the graphophone—an improved version of Edison's original device—which used waxed cardboard instead of tinfoil. Two years later, Edison announced that he had "perfected" the phonograph, although this was far from true. In fact, it was not until the late 1890s, after Edison had established production and recording facilities adjacent to the laboratory, that all the mechanical problems were overcome and the phonograph became a profitable proposition.

In the meantime, Edison conceived the idea of popularizing the phonograph by linking to it in synchronization a zoetrope, a device that gave the illusion of motion to photographs shot in sequence. He assigned the project to William K.L. Dickson, an employee interested in photography, in 1888. After studying the work of various European photographers who also were trying to record motion, Edison and Dickson succeeded in constructing a working camera and a viewing instrument, which were called, respectively, the Kinetograph and the Kinetoscope. Synchronizing sound and motion proved of such insuperable difficulty, however, that the concept of linking the two was abandoned, and the silent movie was born. Edison constructed at the laboratory the world's first motion-picture stage, nicknamed the "Black Maria," in 1893, and the following year Kinetoscopes, which had peepholes that allowed one person at a time to view the moving pictures, were introduced with great success. Rival inventors soon developed screen-projection systems that hurt the Kinetoscope's business, however, so Edison acquired a projector developed by Thomas Armat and introduced it as "Edison's latest marvel, the Vitascope."

Motion pictures

Another derivative of the phonograph was the alkaline storage battery, which Edison began developing as a power source for the phonograph at a time when most homes still lacked electricity. Although it was 20 years before all the difficulties with the battery were solved, by 1909 Edison was a principal supplier of batteries for submarines and electric vehicles and had even formed a company for the manufacture of electric automobiles. In 1912 Henry Ford, one of Edison's greatest admirers, asked him to design a battery for the self-starter, to be introduced on the Model T. Ford's request led to a continuing relationship between these two Americans, and in October 1929 he staged a 50th-anniversary celebration of the incandescent light that turned into a universal apotheosis for Edison.

Most of Edison's successes involved electricity or communication, but throughout the late 1880s and early 1890s the Edison Laboratory's top priority was the magnetic ore-separator. Edison had first worked on the separator when he was searching for platinum for use in the experimental incandescent lamp. The device was supposed to cull platinum from iron-bearing sand. During the 1880s iron ore prices rose to unprecedented heights, so that it appeared that, if the separator could extract the iron from unusable low-grade ores, then abandoned mines might profitably be placed back in production. Edison purchased or acquired rights to 145 old mines in the east and established a large pilot plant at the Ogden mine, near Ogdensburg, N.J. He was never able to surmount the engineering problems or work the bugs out of the system, however, and when ore prices plummeted in the mid-1890s he gave up on the idea. By then he had liquidated all but a small part of his holdings in the General Electric Company, sometimes at very low prices, and had become more and more separated from the electric lighting field.

The magnetic ore-separator

Failure could not discourage Edison's passion for invention, however. Although none of his later projects were as successful as his earlier ones, he continued to work even in his 80s. He died in West Orange on Oct. 18, 1931.

Assessment. The thrust of Edison's work may be seen in the clustering of his patents: 389 for electric light and power, 195 for the phonograph, 150 for the telegraph, 141 for storage batteries, and 34 for the telephone. His life and achievements epitomize the ideal of applied research. He always invented for necessity, with the object of devising something new that he could manufacture. The basic principles he discovered were derived from practical experiments, invariably by chance, thus reversing the orthodox concept of pure research leading to applied research.

Edison's role as a machine shop operator and small manufacturer was crucial to his success as an inventor Unlike other scientists and inventors of the time, who had limited means and lacked a support organization, Edison ran an inventive establishment. He was the antithesis of the lone inventive genius, although his deafness enforced on him an isolation conducive to conception. His lack of managerial ability was, in an odd way, also a stimulant. As his own boss, he plunged ahead on projects more prudent men would have shunned, then tended to dissipate the fruits of his inventiveness, so that he was both free and forced to develop new ideas. Few men have matched him in the positiveness of his thinking. Edison never questioned whether something might be done, only how.

Edison's career, the fulfillment of the American dream of rags-to-riches through hard work and intelligence, made him a folk hero to his countrymen. In temperament he was an uninhibited egotist, at once a tyrant to his employees and their most entertaining companion, so that there was never a dull moment with him. He was charismatic and courted publicity, but he had difficulty socializing and neglected his family. His shafts at the expense of the "long-haired" fraternity of theorists sometimes led formally trained scientists to deprecate him as anti-intellectual; yet he employed as his aides, at various times, a number of eminent mathematical physicists, such as Nikola Tesla and A.E. Kennelly. The contradictory nature of his forceful personality, as well as such eccentricities as his ability to catnap anywhere, contributed to his legendary status. By the time he was in his middle 30s Edison was said to be the best-known American in the world. When he died he was venerated and mourned as the man who, more than any other, had laid the basis for the technological and social revolution of the modern electric world.

BIBLIOGRAPHY. ALFRED O. TATE, *Edison's Open Door: The Life Story of Thomas A. Edison, a Great Individualist* (1938), which tells the story of the early years of the West Orange laboratory, was written by Edison's secretary of the period. FRANCIS JEHL, *Menlo Park Reminiscences*, 3rd ed. (1937–41), is a firsthand account of the 1878–80 period at Menlo Park, by an assistant who came to dislike Edison but was later the first curator at Henry Ford's Edison Institute. THOMAS A. EDISON, *The Diary and Sundry Observations of Thomas A. Edison*, ed. by DAGOBERT D. RUNES (1948, reprinted 1976), provides insight into Edison's feelings and thoughts, especially in the period following the death of his first wife. MATTHEW JOSEPHSON, *Edison: A Biography* (1959), is based on the correspondence and laboratory notebooks in the Edison Laboratory archives, though at the time of its publication the access to the records was severely restricted, which makes the book outdated. ROBERT CONOT, *A Streak of Luck* (1979, reprinted 1986 as *Thomas A. Edison*), is the first comprehensive biography based entirely on the original sources from the West Orange and other depository archives. WYN WACHHORST, *Thomas Alva Edison: An American Myth* (1981), is a revisionist study of Edison's place in the cultural history of the United States, with an extensive bibliography. See also ROBERT FRIEDEL and PAUL ISRAEL, *Edison's Electric Light: A Biography of an Invention* (1986), a well-researched, illustrated account. Archival papers of Edison and his associates are published in *Thomas A. Edison Papers: A Selective Microfilm Edition* (1985–); part 1, for the period 1850–78, and part 2, for 1879–86, have been filmed from the West Orange archives. Subsequent parts will include documents from other repositories.
